²⁰ **Observation of the Higgs boson in the WW^* channel and search
²¹ for Higgs boson pair production in the $b\bar{b}b\bar{b}$ channel with the
²² ATLAS detector**

²³ ABSTRACT

²⁴ This dissertation presents the observation and measurement of the Higgs boson in the $H \rightarrow WW^* \rightarrow$
²⁵ $\ell\nu\ell\nu$ channel at $\sqrt{s} = 7$ TeV and $\sqrt{s} = 8$ TeV and a search for Higgs pair production in the $HH \rightarrow$
²⁶ $b\bar{b}b\bar{b}$ channel at $\sqrt{s} = 13$ TeV with the ATLAS detector in pp collisions at the Large Hadron Collider.

²⁷ First, the discovery of a particle consistent with the Higgs boson in 4.8 fb^{-1} at $\sqrt{s} = 7$ TeV and
²⁸ 5.8 fb^{-1} at $\sqrt{s} = 8$ TeV is discussed. Then, the measurement of the Higgs boson signal strength
²⁹ and cross section in both the gluon fusion and vector boson fusion (VBF) production modes using
³⁰ 20.3 fb^{-1} of $\sqrt{s} = 8$ TeV data combined with 4.8 fb^{-1} of 7 TeV data is shown. The combined signal
³¹ strength is measured to be $\mu = 1.09^{+0.23}_{-0.21}$. The total observed significance of the $H \rightarrow WW^*$ process
³² is observed to be 6.1σ (with 5.8σ expected). Advanced methods for background reduction and estima-
³³ tion, particularly in same-flavor lepton final states, are shown. The VBF signal strength is measured to
³⁴ be $\mu_{\text{VBF}} = 1.27^{+0.53}_{-0.45}$ with an observed significance of 3.2σ (with 2.7σ expected). In the VBF chan-
³⁵ nel, a selection requirement based method, the precursor to the final multivariate technique used for the
³⁶ result, is detailed.

³⁷ Finally, a search for Higgs pair production in the $b\bar{b}b\bar{b}$ final state with 3.2 fb^{-1} at $\sqrt{s} = 13$ TeV is
³⁸ presented. A particular focus is placed on a tailored signal region for resonant production of Higgs pairs
³⁹ at high masses. No significant excesses are observed, and upper limits on cross sections are placed for
⁴⁰ spin-2 Randall Sundrum gravitons (RSG) and narrow spin-0 resonances. The cross section of $\sigma(pp \rightarrow$
⁴¹ $G_{\text{KK}}^* \rightarrow hh \rightarrow b\bar{b}b\bar{b})$ with $k/\bar{M}_{\text{Pl}} = 1$ is constrained to be less than 70 fb for masses in the range
⁴² $600 < m_{G_{\text{KK}}^*} < 3000 \text{ GeV}$. The cross section upper limits for $\sigma(pp \rightarrow H \rightarrow hh \rightarrow b\bar{b}b\bar{b})$ ranges
⁴³ from 30 to 300 fb in the mass range of $500 < m_H < 3000 \text{ GeV}$.

179	3.8	Predicted backgrounds (compared with data) as a function of the number of jets, n_j (a)	
180		and b), and the number of b -tagged jets, n_b (c), after pre-selection requirements. Panel a	
181		shows n_j in the same flavor sample, while panels b and c show the n_j and n_b distributions	
182		in the different flavor sample.	61

183	3.9	An event display of a Z/γ^* + jets event illustrating the effect of pileup interactions	63
184	3.10	The RMS of different missing transverse momentum definitions as a function of the average number of interactions per bunch crossing	63
185	3.11	The difference between the true and reconstructed values of the missing transverse momentum (a) and m_T (b) in a gluon fusion signal sample using both track-based (p_T^{miss}) and calorimeter-based E_T^{miss} definitions.	65
186	3.12	Comparison of f_{recoil} distributions for $Z/\gamma^* + \text{jets}$, $H \rightarrow WW^*$, and other backgrounds with real neutrinos.	66
187	3.13	Signal significance as a function of required value for f_{recoil} and $p_{T,\text{rel}}^{\text{miss}(\text{trk})}$ in the ggF $H \rightarrow WW^*$ with $n_j = 0$	67
193	4.1	Jet multiplicity distribution in data and MC after applying lepton, jet, and $E_{T,\text{rel}}^{\text{miss}}$ selections. The WW and top backgrounds have been normalized using control samples, and the hashed band indicates the total uncertainty on the prediction [1].	74
194	4.2	Comparison of m_T between data and simulation in the $n_j = 0$ WW (a) and $n_j = 1$ top (b) control samples [1].	76
195	4.3	m_T distribution in the $H \rightarrow WW \rightarrow e\nu\mu\nu$ $n_j \leq 1$ channels for 8 TeV data [1].	78
196	4.4	Diphoton mass spectrum in 7 and 8 TeV data. Panel a) shows the unweighted data distribution superimposed on the background fit, while panel c) shows the data where each event category is weighted by its signal to background ratio. Panels b) and d) show the respective distributions with background subtracted [1].	79
203	4.5	Four lepton invariant mass spectrum ($m_{4\ell}$) in 7 and 8 TeV data compared to background estimate. A 125 GeV SM Higgs signal is shown in blue [1].	80
204	4.6	Local p_0 distribution as a function of hypothesized Higgs mass for the $H \rightarrow ZZ^* \rightarrow 4\ell$ (a), $H \rightarrow \gamma\gamma$ (b), and $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ (c) channels. Dashed curves show expected results, while solid curves show observed. Red curves are from 7 TeV data, blue curves from 8 TeV, and black curved combined [1].	82
209	4.7	Combined 95% CL limits (a), local p_0 values (b), and signal strength measurement (c) as a function of Higgs mass [1].	83
211	4.8	Comparison of measured signal strength μ for a 126 GeV Higgs in the 7 and 8 TeV datasets [1].	84
212	4.9	Two dimensional likelihood as a function of signal strength μ and Higgs mass m_H [1]. . .	84
213	5.1	A comparison of the subleading lepton p_T spectrum between VBF $H \rightarrow WW^*$ production and $t\bar{t}$ background.	87
215	5.2	Leading jet η in VBF $H \rightarrow WW^*$ (red) and $t\bar{t}$ (black)	96
216	5.3	Distributions of (a) m_{jj} , (b) Δy_{jj} , (c) $C_{\ell 1}$, and (d) $\Sigma m_{\ell j}$, for the cut-based VBF analysis. The top panels compare simulation and data, while the bottom panels show normalized distributions for all background processes and signal for shape comparisons [74].	97

219	5.4	A cartoon of the WW final state. Momenta are represented with thin arrows, spins with thick arrows [74].	98
220	5.5	Event display of a VBF candidate event [74].	100
221	5.6	Higgs topology variables - $m_{\ell\ell}$ (top left), $\Delta\phi_{\ell\ell}$ (top right), and m_T (bottom) - used in the selection requirements of the cut-based signal region and as inputs to the BDT result. These are plotted after all of the BDT pre-training selection cuts [74]. The VBF Higgs signal cross section is multiplied by a factor of 50 to allow for shape comparisons.	102
222	5.7	VBF topology variables - m_{jj} (top left), Δy_{jj} (top right), $\sum C_\ell$ (bottom) - used in the selection requirements of the cut-based signal region and as inputs to the BDT result. These are plotted after all of the BDT pre-training selection cuts [74]. The VBF Higgs signal cross section is multiplied by a factor of 50 to allow for shape comparisons.	103
223	5.8	Distributions of m_{jj} (a) and O_{BDT} (b) in the VBF $n_b = 1$ top CR [74].	105
224	5.9	Comparison of m_{jj} shape in a same flavor $Z \rightarrow \ell\ell$ control region and the VBF cut-based signal region. The MC samples used for these distributions are given in table 5.4.	106
225	5.10	General illustration of the ABCD region definitions for $Z/\gamma^* \rightarrow \ell\ell$ background estimation.	107
226	5.11	Distribution of m_{T2} in the WW validation region of the VBF analysis [74].	109
227	5.12	Extrapolation factors for the $W + \text{jets}$ estimate derived for muons (a) and electrons (b) as a function of lepton p_T [74]. OC refers to the opposite charge $W + \text{jets}$ MC sample, while SC refers to the same charge $W + \text{jets}$ MC. The uncertainty bands have contributions from statistical uncertainty in the data and backgrounds to $Z + \text{jets}$ that are subtracted from the data, as well as systematic uncertainties due to variations in the extrapolation factor between the three MC samples shown.	III
228	5.13	Background composition in final VBF signal region [74].	112
229	5.14	Variations in the top background extrapolation factor in the cut-based analysis due to PDF uncertainties. The uncertainties are shown in the three bins of m_T used in the final cut-based statistical fit. Variations from the eigenvector of the nominal PDF, CT10, as well as the result from an alternate PDF (NNPDF10), are compared.	115
230	5.15	Variations in the top background extrapolation factor in the cut-based analysis due to QCD scale uncertainties. The uncertainties are shown in the three bins of m_T used in the final cut-based statistical fit. Q_F is the QCD factorization scale, while Q_R is the QCD renormalization scale.	115
231	5.16	Post-fit distributions in the cut-based VBF analysis. Panel (a) shows the one-dimensional m_T distribution, while (b) shows the data candidates split into the bins of m_T and m_{jj} used in the final fit [74].	118
232	5.17	Postfit distributions in the BDT VBF analysis [74].	119
233	5.18	Overlap between cut-based and BDT VBF signal region candidates in the m_{jj} - m_T plane. .	119
234	6.1	Post-fit m_T distribution in the $n_j \leq 1$ regions for the same flavor ($ee/\mu\mu$) final states [74].	122

256	6.2 Post-fit m_T distribution in the $n_j \leq 1$ regions [74].	124
257	6.3 Best fit signal strength $\hat{\mu}$ as a function of hypothesized m_H [74].	125
258	6.4 Local p_0 as a function of m_H [74].	126
259	6.5 Likelihood as a function of $\mu_{\text{VBF}}/\mu_{\text{ggF}}$ [74].	126
260	6.6 Two dimensional likelihood scan as a function of μ_{VBF} and μ_{ggF} [74].	127
261	6.7 Likelihood scan as a function of κ_F and κ_V , the Higgs coupling scale factors [74].	129
262	6.8 Comparison of signal strength measurements in different Higgs decay channels on ATLAS [108].	131
263	7.1 Parton luminosity ratios as a function of resonance mass M_X for 13/8 TeV and 7/8 TeV [109].	134
264	7.2 Summary of HH branching ratios [110].	135
265	7.3 Minimum ΔR between B decay vertices for different RSG masses in a $G_{\text{KK}}^* \rightarrow HH \rightarrow$	
266	$4b$ sample with $c = 1$	136
267	7.4 Trigger efficiency for events passing all signal region selections as a function of mass in	
268	$G_{\text{KK}}^* \rightarrow HH \rightarrow 4b$ samples with $c = 1$ [119]. In the trigger names, “j” refers to a jet	
269	or jets. “ht” refers to H_T , the scalar sum of transverse momenta in the event. “bloose”	
270	refers to a loose b -tagging requirement applied to the jet. “aor” refers to anti- k_T jets with	
271	$R = 1.0$. The numbers at the end of each trigger name are the thresholds on the given	
272	quantity in GeV.	138
273	7.5 Comparison of untrimmed and trimmed jet masses for large radius jets in a RSG sample	
274	with $m_{G_{\text{KK}}^*} = 1$ TeV. JES (JMS) refers to the standard jet energy (mass) scale calibration	
275	for ATLAS [69].	139
276	7.6 Efficiency of finding two b -jets from each Higgs in an RSG event using calorimeter jets	
277	with $R = 0.3$ and track jet radii of $R = [0.2, 0.3, 0.4]$ [123].	140
278	7.7 Illustration of the boosted selection requirements on Higgs candidates. Each large-radius	
279	calorimeter jet (Higgs candidate) must contain two track jets.	142
280	7.8 Estimated significance as a function of signal mass for RSG $c = 1$ models in the $3b$ (a) and	
281	$4b$ (b) regions for different b -tagging efficiency working points	143
282	7.9 Acceptance \times efficiency as a function of mass for (a) RSG and (b) narrow heavy scalar	
283	signal models [126].	144
284	7.10 Efficiency of requiring 3 or 4 b -tagged track jets vs. RSG mass. The efficiency quoted is	
285	relative to the previous selection requirements (rather than an absolute efficiency).	145
286	7.11 MV2c20 b -tagging efficiency for each of the four track jets in the boosted $4b$ selection as a	
287	function of RSG mass for $c = 1$ models.	146
288	7.12 M_J^{sublead} vs. M_J^{lead} in a 2 b -tag data sample. The signal region is defined by the inner black	
289	contour ($X_{hh} < 1.6$) and the sideband region is defined by the outer contour ($R_{hh} >$	
290	35.8 GeV). The region between the black contours is the control region. The mass region	
291	which is enriched in $t\bar{t}$ background is also shown for illustration [126].	147
292	7.13 An illustration of the data-driven background estimation technique for the boosted analysis	149

293	7.14	Leading large-R jet mass in the $3b$ (a) and $4b$ (b) sideband regions. The multijet and $t\bar{t}$ backgrounds are estimated using the data-driven methods described above. Because their normalizations are derived in the sideband region, the total background normalization is constrained by default to match the normalization of the data [126].	150
294			
295	7.15	Di-jet invariant mass (M_{2J}) in the $3b$ (a) and $4b$ (b) control regions. The multijet and $t\bar{t}$ backgrounds are estimated using the data-driven methods described above [126].	151
296			
297	7.16	Di-jet invariant mass (M_{2J}) in the $3b$ (a) and $4b$ (b) signal regions. The multijet and $t\bar{t}$ backgrounds are estimated using the data-driven methods described above. In the $3b$ region, a graviton signal with $m_{G_{KK}^*} = 1.8$ TeV and $c = 1$ is overlaid, with the cross section multiplied by a factor of 50 so that the signal is visible. In the $4b$ region, signals with $m_{G_{KK}^*} = 1.0$ TeV and $m_{G_{KK}^*} = 1.5$ TeV are overlaid, both with $c = 1$ and the yields multiplied by factors of 2 and 5 respectively [126].	156
298			
299	8.1	Di-jet invariant mass (M_{2J}) in the resolved signal region. A graviton signal with $m_{G_{KK}^*} = 800$ GeV and $c = 1$ is overlaid. [126].	159
300			
301	8.2	Expected and observed upper limit as a function of mass for G_{KK}^* in the RSG model with (a) $c = 1$ and (b) $c = 2$, as well as (c) H with fixed $\Gamma_H = 1$ GeV, at the 95% confidence level in the CL_s method [126].	162
302			
303	9.1	Combined ATLAS and CMS measurements in Run 1 for (a) Higgs signal strength in gluon fusion and VBF and (b) Higgs couplings normalized to their SM predictions	166
304			
305	9.2	Discovery significance for RSG models at the HL-LHC in three different budget scenarios [133]. Systematic uncertainties on the background prediction (σ_B) of 2.5% and 5.0% are both tested.	167
306			
307	A.1	p_T of the leading track jet in the leading calorimeter jet for different signal masses in RSG $c = 1$ models	169
308			
309	A.2	MV2c2o score for the leading track jet (a) and subleading track jet (b) of the leading calorimeter jet for different signal masses in RSG $c = 1$ models	169
310			
311	A.3	IP3D log-likelihood ratio ($\log(p_b/p_u)$) of the leading track jet in the leading calorimeter jet for different signal masses in RSG $c = 1$ models	170
312			
313	A.4	Mass (a) and number of tracks (b) for the secondary vertices computed with the SV1 algorithm. When no secondary vertex is found, the quantities are assigned to default negative values.	171
314			
315	A.5	Mass (a) and number of tracks (b) for vertices computed with the JetFitter algorithm. When no vertices are found, the quantities are assigned to default negative values.	171
316			
317	A.6	MV2c2o score (a) and SV1 mass (b) for leading track jets with two truth b quarks ($n_{tb,lead} = 2$) compared to those with only one truth b ($n_{tb,lead} = 1$).	172
318			

328	A.7 Track fit χ^2/n_{DOF} (a) and number of pixel detector hits (b) for the leading track of the	
329	leading track jet in different mass RSG $c = 1$ samples	173
330	A.8 MV _{2c2o} score (a) and SV1 mass (b) for leading track jets whose leading track jet has at least	
331	four pixel hits ($N_{\text{pix}} \geq 4$) compared to those which do not ($N_{\text{pix}} < 4$).	174

Listing of tables

332

333	1.1	Production cross sections for a 125 GeV Higgs boson at $\sqrt{s} = 8$ TeV with scale and PDF uncertainties [18].	13
334	1.2	Theoretical branching ratios for a 125 GeV Higgs boson, quoted as a percentage of the total width of the Higgs. Uncertainties shown are relative to the branching ratio value [18].	15
335	1.3	Possible channels for Higgs searches. Checkmarks denote the most sensitive production modes for each decay channel [5].	16
336	1.4	Production cross sections for pair production of a 125 GeV Higgs boson at $\sqrt{s} = 14$ TeV with total uncertainty [29]. The uncertainties include QCD scale and PDF variations as well as uncertainties on α_S	17
337	2.1	Evolution of LHC machine conditions [50, 51].	26
338	2.2	Performance requirements for the ATLAS detector [44].	37
339	2.3	Signal efficiencies for WH production with $H \rightarrow b\bar{b}$ and $H \rightarrow WW^* \rightarrow \mu\nu qq$ under different trigger configurations [57].	42
340	3.1	A summary of backgrounds to the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ signal	59
341	4.1	Monte carlo generators used to model signal and background for the Higgs search [1].	73
342	4.2	Normalization factors (ratio of data and MC yields in a control sample) for the Standard Model WW and top backgrounds in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis [1]. Only statistical uncertainties are shown.	76
343	4.3	Data and expected yields for signal and background in the final $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ signal region. Uncertainties shown are both statistical and systematic [1].	77
344	4.4	Summary of the expected and observed significance and measured signal strengths in the combined 7 and 8 TeV datasets for the Higgs discovery analysis [1].	81
345	5.1	Single lepton triggers used for electrons and muons in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis. A logical “or” of the triggers listed for each lepton type is taken. Units are in GeV, and the i denotes an isolation requirement in the trigger.	88
346	5.2	Di-lepton triggers used for different flavor combinations in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis. The two thresholds listed refer to leading and sub-leading leptons, respectively. The di-muon trigger only requires a single lepton at level-1.	88

361	5.3	Trigger efficiency for signal events and relative gain of adding a dilepton trigger on top of the single lepton trigger selection. The first lepton is the leading, while the second is the sub-leading. Efficiencies shown here are for the ggF signal in the $n_j = 0$ category but are comparable for the VBF signal.	88
362			
363			
364	5.4	Monte Carlo samples used to model the signal and background processes [74]. The ta- ble lists the cross section for each process, taking into account the branching ratio for the process producing two leptons.	90
365			
366			
367	5.5	p_T dependent isolation requirements for muons. Muons are required to have their calorime- ter based or track based cone sums be less than this fraction of their p_T	92
368			
369			
370	5.6	p_T dependent requirements for electrons. Electrons are required to have their calorimeter based or track based cone sums be less than this fraction of their E_T	92
371			
372	5.7	Summary of event selection for the $n_j \geq 2$ VBF analysis in the 8 TeV cut-based analy- sis [74].	99
373			
374	5.8	Background composition after each requirement in the $n_j \geq 2$ VBF analysis in the 8 TeV cut-based analysis [74].	100
375			
376	5.9	Top normalization factors computed at each stage of the cut-based selection. Uncertainties are statistical only.	104
377			
378	5.10	Top normalization factors computed for each bin of O_{BDT} . Uncertainties are statistical only.	104
379			
380	5.11	$Z/\gamma^* \rightarrow \tau\tau$ correction factors for the VBF cut-based analysis. Uncertainties are statistical only.	107
381			
382	5.12	$Z/\gamma^* \rightarrow \ell\ell$ normalization factors for cut-based and BDT analyses. Uncertainties are statistical only.	108
383			
384	5.13	Systematic uncertainties for various processes in the cut-based VBF analysis, given in units of % change in yield. Values are given for the low m_{jj} signal region.	114
385			
386	5.14	Composition of the post-fit uncertainties (in %) on the total signal (N_{sig}), total back- ground (N_{bkg}), and individual background yields in the VBF analysis [74].	116
387			
388	5.15	Event selection for the VBF BDT analysis. The event yields in (a) are shown after the pre- selection and the additional requirements applied before the BDT classification (see text). The event yields in (b) are given in bins in O_{BDT} after the classification [74].	117
389			
390			
391	6.1	Post-fit yields in ggF dedicated signal regions for the $ee/\mu\mu$ final states [74].	121
392	6.2	All signal regions definitions input into final statistical fit [74].	123
393	6.3	Post-fit yields in the both ggF and VBF dedicated signal regions with all lepton flavor final states combined [74].	123
394			
395	7.1	Summary of requirements on objects used in the $X \rightarrow HH \rightarrow b\bar{b}b\bar{b}$ search	141

396	7.2 Effect of boosted selection on data, RSG signal models, $t\bar{t}$, and $Z+jets$. The numbers 397 from simulation are normalized with the MC generator cross section and do not take into 398 account the data driven estimates described in section 7.6 [127].	146
399	7.3 Mass region definitions used for background estimation.	148
400	7.4 Parameters derived for exponential fit to background M_{2J} shape in the $3b$ and $4b$ signal 401 regions [127].	150
402	7.5 The number of events in data and predicted background events in the boosted 3-tag and 403 4-tag sideband and control regions [126]. The uncertainties shown are statistical only.	151
404	7.6 Summary of systematic uncertainties in the total background and signal event yields (ex- 405 pressed in %) in the boosted 3-tag and 4-tag signal regions. Systematic uncertainties on 406 the signal normalization are shown for models with $m_{G_{KK}^*} = 1.5$ TeV and both $c = 1$ 407 and $c = 2$ as well as a narrow width heavy scalar.	153
408	7.7 Alternate fit functions used to model the M_{2J} distribution in the QCD multijet back- 409 ground. In the equations, $x = M_{2J}/\sqrt{s}$	154
410	7.8 Observed yields in the 3-tag and 4-tag signal regions for the boosted analysis compared to 411 the predicted number of background events Errors correspond to the total uncertainties 412 in the predicted event yields. The yields for a graviton with $m_{G_{KK}^*} = 1$ TeV and $c = 1$ 413 are also shown [126].	155
414	8.1 Observed yields in the resolved selection 4-tag signal region compared to the predicted 415 number of background events Errors correspond to the total uncertainties in the pre- 416 dicted event yields. The yields for a graviton with $m_{G_{KK}^*} = 800$ GeV and $c = 1$ are 417 also shown [126].	158

Acknowledgments

420 I have been a member of the Harvard ATLAS group for many years now, first as an undergraduate and
421 then as a graduate student. As a result, I have had the privilege of interacting with many amazing people
422 there over the years and have accumulated a large list of folks to thank.

423 First and foremost, I must thank the two people who have effectively been my academic parents since I
424 started in the Harvard group: João Guimarães da Costa and Melissa Franklin. Melissa Franklin and João
425 Guimarães da Costa. They have both been so important to both my academic and personal development
426 that I can't even put one before the other. João has been an excellent PhD advisor, showing me how to
427 look at the big picture and helping me navigate the sometimes complicated politics of ATLAS. He got me
428 started on my first projects with ATLAS as a young college sophomore before there was even beam in the
429 LHC (go cosmic ray muons!). He has also been a constant source of advice and support, even when we
430 have been on different continents. Melissa gave me my start in HEP as a summer student on CDF and
431 has been an unbelievable mentor throughout my time at Harvard. I still remember our weekly chalkboard
432 particle physics lessons after that first summer. She also graciously took me on as a co-advisee after João
433 moved on to his new position at IHEP. I am incredibly lucky to have had both of them as advisors.

434 Another mentor who was essential to my development as a graduate student is Paolo Giromini. His un-
435 canny knowledge and intuition about detectors is unmatched and I am very grateful to have had the chance
436 to work with him on the micromegas for the ATLAS New Small Wheel upgrade project. I owe essentially
437 all my practical knowledge about detectors (and building things in general) to him. I also appreciated his
438 unique sense of humor which made sometimes difficult tasks much easier to get through.

439 I am grateful to John Huth and Masahiro Morii for their helpful advice as the other professors in the
440 Harvard ATLAS group as well. I especially thank John for helping me get started on the micromegas
441 trigger project and being a great professor to TF particle physics for. Additionally I thank Howard Georgi
442 for serving as my third committee member and offering me feedback throughout my graduate career.

443 I also owe enormous thanks to Hugh Skottowe, the postdoc that I worked most closely with in my early
444 years as a graduate student. He was always able to help me through complicated tasks in everything from
445 writing code to understanding difficult physics concepts. I particularly enjoyed walking down to his office
446 in Palfrey at random times and talking through whatever problem I was tackling on that day.

447 Alex Tuna, the second postdoc that I worked closely with at Harvard, deserves great thanks as well. He
448 helped me push through to the end of my graduate career and offered great advice along the way.

449 Being at Harvard, I have seen an incredible array of graduate students graduate before me: Ben Smith,
450 Verena Martinez Outschoorn, Srivas Prasad, Michael Kagan, Giovanni Zevi Della Porta, Laura Jeanty,
451 Kevin Mercurio, William Spearman, and Andy Yen. I want to thank them all for showing me what a good
452 physicist looks like and for patiently answering my questions and offering insightful advice about physics
453 and life.

454 Getting through graduate school would not have been possible without the support and friendship of
455 the other students in our group. Thanks to Emma Tolley for geeking out with me about cool comput-
456 ing stuff, going to taste delicious beers with me, and helping start the Palfrey tradition of Taco Tuesdays.
457 Thanks to Brian Clark for being a great friend and housing companion both in Kirkland House and in our
458 tiny summer apartment in Geneva (and thanks to his partner Allison Goff for the same reasons!). Thanks
459 to Siyuan Sun for giving me my first aikido lesson and always being there for great conversations, big and
460 small. Tony (Baojia) Tong deserves special recognition for working with me on the $4b$ analysis and putting
461 up with my sometimes strange requests (and giving me rides to the Val Thoiry Migros so I wouldn't have
462 to pay exorbitant Geneva grocery prices!). Stephen Chan is probably the only student in the group who
463 both understands my references to the Sopranos and makes some of his own. To the younger graduate
464 students - Karri Di Petrillo, Jennifer Roloff, Julia Gonski, and Ann Wang - I want to say thank you for
465 making the group a fun and lively place to be and giving all of us energy that the older graduate students
466 like myself can sometimes lack.

467 I'd like to thank Annie Wei and Gray Putnam, the two undergraduates I have worked with as a graduate
468 student. Their unbelievable intuition and quickness in picking up difficult particle physics concepts is
469 inspiring.

470 I would also like to thank all of the postdocs that I have interacted with in my time in the Harvard group:
471 Kevin Black, Alberto Belloni (who would always ask me “Do you have it?”...I can now say that I do!),
472 Shulamit Moed, Corrinne Mills, Geraldine Conti, David Lopez Mateos, Chris Rogan, Valerio Ippolito,
473 and Stefano Zambito.

474 There are many people on ATLAS who have helped me get to this point as well. In the *WW* group, I
475 have to thank Jonathan Long, Joana Machado Miguens, Ben Cerio, Philip Chang, Bonnie Chow, Richard
476 Polifka, Heberth Torres, Tae Min Hong, and Jennifer Hsu for being wonderful colleagues and making the
477 entire analysis run smoothly. In the *4b* group, I have to thank Qi Zeng, Tony Tong, Alex Tuna, Michael
478 Kagan, Max Bellomo, John Alison, and Patrick Bryant.

479 Kirkland House was my home for the last three years of graduate school and was an wonderful envi-
480 ronment and support system. I want to thank my fellow tutors, especially Brian Clark and Allison Goff
481 (again), Zach Abel, Kelly Bodwin, Alex Lupsasca, John and Pam Park, Luke and Erin Walczewski, and
482 Philip Gant for their friendship and support. I also want to thank Kate Drizos Cavell, Bob Butler, and the
483 Faculty Deans Tom and Verena Conley.

484 There are still a few friends that haven’t been covered yet and deserve great thanks. Jake Connors and
485 Meredith MacGregor have been absolutely wonderful friends and I thank them in particular for the many
486 home-cooked meals and great conversations we’ve had in their apartment. Nihar Shah has been my friend
487 and confidant since we were both wee freshmen in Harvard Yard. Gareth Kafka, though he sits on the
488 “neutrino” side of Palfrey House, has made days there more fun and has also been an enthusiastic partici-
489 pant in the Palfrey Taco Tuesdays.

490 Being at Harvard necessarily means having to navigate through bureaucracy at some point or another.
491 I thank Lisa Cacciabuado, Carol Davis, Jacob Barandes, Korin Watras, and Angela Allen for always having
492 open doors and being the most kind, helpful people in the Physics department.

493 I thank Venky Narayananuriti for putting on a great SPU course that I was proud to be a part of and
494 TF for. I’d also like to thank Jim Waldo for offering me much advice about working in Computer Science
495 and giving me a fun data project to be a part of in my free time.

496 I grew up in a very tight knit Serbian community on the south side of Chicago which helped make me

497 the person I am today. I would like to thank all of the people at St. Simeon Mirotochivi Serbian Orthodox
498 Church who have always been sources of enthusiasm and support in my life.

499 I would not be here without the unconditional love and constant support and encouragement of my
500 family. To my pokojni Deda Branko and Miloje, my pokojni Baba Milka, and my Baba Desa, I want to
501 say thank you for instilling in me at an early age the love of curiosity and storytelling that I have carried
502 throughout my life. To my sister Angelina, I want to say thank you for always loving me and being my
503 partner in crime throughout our childhoods. To my parents, Miroljub and Nada, Tata and Mama, I really
504 cannot express how grateful I am to you and how much I owe you. As I look back now I see how I am
505 a combination of both of your best qualities. Every day I am in situations where I better understand the
506 lessons you taught me and the sacrifices you made to make sure I got the best possible education. I love
507 you all.

508 Finally, I have to thank my soul mate, the one person in my life who understands me more than anyone
509 else, my fiancée Kelly Brock. You are my sounding board, my support system, my cheerleader (figuratively
510 and literally!), my best friend, my role model, and my everything. I would not have gotten through grad-
511 uate school without you and my life would not be the same without you. I cannot wait to start our new
512 lives together as the married doctors, tackling whatever comes our way with the same zeal with which we
513 tackled graduate school. I love you with all my heart and soul.

515

Introduction

516 The Higgs boson is often described as one of the cornerstones of particle physics. When the Standard
517 Model was first developed as a theory to describe the fundamental particles and forces of nature, physicists
518 were faced with a dilemma. The electroweak theory beautifully characterized both electromagnetism and
519 the weak force with a single underlying framework. However, the mass of the weak W and Z bosons
520 was puzzling given the fact that their electromagnetic counterpart, the photon, is massless. The Higgs
521 mechanism was developed as the leading theory for the origin of this electroweak symmetry breaking. It
522 predicted the existence of an additional spin-0 boson in the Standard Model, the Higgs boson. Generations
523 of collider experiments searched for this elusive particle. This dissertation presents research work on the
524 Higgs boson from its discovery to its use as a tool in the search for physics beyond the Standard Model
525 with the ATLAS detector at the Large Hadron Collider (LHC).

526 One of the first priorities for the LHC when it began colliding proton beams in 2010 was the search
527 for the Higgs boson. This search was initially tackled in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel, followed by

528 the $H \rightarrow \gamma\gamma$ and $H \rightarrow ZZ^* \rightarrow 4\ell$ channels. Each channel has its own merits, but the WW^* mode is
529 particularly suited to searching over a wide range of masses. The $H \rightarrow WW^*$ branching ratio is large and it
530 is the primary decay channel above the $2m_W$ mass threshold. Despite the fact that the full Higgs invariant
531 mass cannot be reconstructed in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel, its signal to background ratio makes
532 it ideal for measurement of Higgs properties such as the production cross section and couplings.

533 In 2012, the ATLAS and CMS experiments announced the discovery of a new particle consistent with
534 the Higgs boson [1, 2]. In ATLAS, this discovery was made with 4.8 fb^{-1} collected at $\sqrt{s} = 7 \text{ TeV}$
535 and 5.8 fb^{-1} at $\sqrt{s} = 8 \text{ TeV}$. This dissertation first presents the search for gluon fusion production
536 of the Higgs in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel, which played an important role in this discovery.
537 Selection requirements which were optimized to maximize the discovery significance in this channel, as
538 well as background estimation procedures, are discussed.

539 After its discovery, interest in the Higgs shifted to focus on the measurement of its properties. As a result,
540 extensions of the initial discovery analysis in larger datasets had two main goals. Improvement of signal
541 to background ratio was important to allow for precision measurements. Also, searches for production
542 modes of the Higgs with lower cross sections than gluon fusion were a priority. The first such extension
543 presented in this dissertation is a tailored selection for $\ell\nu\ell\nu$ final states with same flavor leptons. Novel
544 variables for the reduction of the $Z+\text{jets}$ background that could remain robust under increasing LHC
545 instantaneous luminosities are shown. The second post-discovery result shown is the first evidence of
546 Vector Boson Fusion (VBF) production of the Higgs boson.

547 VBF production of the Higgs boson is particularly interesting in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ final state.
548 In this combination of production and decay modes, the Higgs boson couples exclusively to vector bosons,
549 allowing for precise measurement of the Higgs- W coupling constant. However, it is challenging to observe
550 VBF Higgs production because its cross section at the LHC is an order of magnitude lower than gluon
551 fusion production. The large $H \rightarrow WW^*$ branching ratio thus presents another advantage over other
552 final states. Additionally, VBF production of the Higgs boson creates two forward jets in addition to the
553 Higgs, and these jets can be used to isolate VBF Higgs events from other production modes. The VBF
554 $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis first created a selection requirement based signal region using variables

constructed specifically for the VBF Higgs production topology. This “cut-based” analysis is presented in detail in this dissertation. These VBF topology variables, once validated in the cut-based analysis, were then input into a multivariate boosted decision tree discriminant to achieve the first evidence of VBF Higgs production with the full 20.3 fb^{-1} of $\sqrt{s} = 8 \text{ TeV}$ data in ATLAS. Additionally, combining these results with the dedicated gluon fusion Higgs production analysis allowed for precise measurement of the Higgs couplings.

After a two year shutdown, the LHC restarted in 2015 with a center of mass energy of $\sqrt{s} = 13 \text{ TeV}$. This increase improved the LHC’s ability to probe for physics beyond the Standard Model, and the Higgs sector remained one of the largest regions of unprobed phase space where such new physics could be discovered. Production of high mass resonances benefit most from the center of mass energy increase. In particular, the cross section for a generic gluon-initiated 2 TeV resonance increased tenfold with the increase from 8 to 13 TeV . Therefore, a natural next step in studies of the Higgs was a search for a new heavy resonance which decays into a pair of Higgs bosons. The final result shown in this dissertation is a search for resonant di-Higgs production in the $X \rightarrow HH \rightarrow b\bar{b}b\bar{b}$ final state with 3.2 fb^{-1} recorded by ATLAS at $\sqrt{s} = 13 \text{ TeV}$. This search has the unique advantage that it can both probe new physics and gain further understanding of the Higgs potential through constraints on SM pair production of the Higgs. It also extends the previous ATLAS results at $\sqrt{s} = 8 \text{ TeV}$ and probes higher mass resonances that were not previously accessible. Additionally, it is an informative precursor to di-Higgs analyses at the future High Luminosity LHC (HL-LHC), where a projected dataset of 3000 fb^{-1} at $\sqrt{s} = 14 \text{ TeV}$ will begin to become sensitive to the SM Higgs self coupling.

As mentioned above, this dissertation begins by discussing the discovery of the Higgs and the role of the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel. It then presents the first evidence for the VBF production mode using the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel with the full ATLAS Run 1 dataset. It also shows the final combined Run 1 measurements of gluon fusion Higgs production from this channel. Finally, it presents a search for Higgs pair production in the $HH \rightarrow b\bar{b}b\bar{b}$ channel. It is organized into four parts.

Part 1 presents the theoretical and experimental background required for the subsequent parts. Chapter 1 gives an overview of Higgs physics, particularly single and double Higgs production in the Standard

582 Model and beyond. Chapter 2 presents details regarding the Large Hadron Collider and the ATLAS experi-
583 ment. The evolution of machine conditions, descriptions of the ATLAS sub-detectors, and an overview of
584 object reconstruction in ATLAS are all shown. A brief interlude on the ATLAS Muon New Small Wheel
585 upgrade is also given, as this upgrade has been a focus of my graduate work and will have an important
586 impact on ATLAS' ability to study the Higgs at the High Luminosity LHC.

587 Part 2 discusses the observation and measurement of the Higgs in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel
588 in the ATLAS Run 1 dataset at $\sqrt{s} = 7$ and 8 TeV. Because I worked in this channel from before the
589 discovery through to the final analysis of the Run 1 dataset, Part 2 is organized in such a way to allow
590 easy presentation of multiple analyses on different subsets of the full Run 1 dataset. Chapter 3 presents
591 a general overview of the $H \rightarrow WW^*$ analysis strategy and defines many of the variables and common
592 elements used in the rest of Part 2. Chapter 4 presents the discovery and subsequent measurements of
593 the Higgs boson, focusing on the role of the WW^* channel in this discovery. Chapter 5 presents the
594 first evidence for the VBF production mode of the Higgs, a result from the WW^* channel in the full
595 Run 1 ATLAS dataset. In this chapter, the focus is mainly on the cut-based VBF analysis. The cut-based
596 analysis was an important first step to the final VBF result which used a boosted decision tree. Where
597 appropriate, connections between the cut-based and BDT analyses are shown and their compatibility is
598 discussed. Finally, the VBF analysis was an important input into the combined Run 1 $H \rightarrow WW^* \rightarrow$
599 $\ell\nu\ell\nu$ result, which used both the gluon fusion and VBF channels in a combined fit to infer properties of
600 the Higgs, including its couplings to the gauge bosons and its production cross section. This is the topic
601 of Chapter 6.

602 Part 3 presents a search for Higgs pair production in the $HH \rightarrow b\bar{b}b\bar{b}$ channel. Chapter 7 presents
603 an overview of this search in the boosted regime, where the Higgs pairs are the result of the decay of a
604 heavy resonance. Chapter 8 shows the combined results between the boosted regime and the resolved
605 regime, which is sensitive to lower mass resonances and non-resonant Higgs pair production. Finally, Part
606 4 presents a conclusion and brief outlook of future Higgs physics with ATLAS.

610

The Physics of the Higgs Boson

611 This chapter presents an overview of the Standard Model of Particle Physics and in particular the physics
612 of the Higgs boson. First, a brief overview of the Standard Model is presented. Then, a description of
613 the Higgs mechanism of electroweak symmetry breaking is given. Next, the physics of single Higgs boson
614 production and decay is described. The Standard Model also allows for production of two Higgs bosons
615 and this is detailed as well. Finally, di-Higgs production in two beyond the Standard Model (BSM) theories
616 - Randall-Sundrum gravitons (RSG) and Two Higgs Doublet Models (2HDM) - is shown.

617 **I.I THE STANDARD MODEL OF PARTICLE PHYSICS**

618 The Standard Model (SM) of Particle Physics is a quantum field theory describing the fundamental parti-
619 cles of nature and the forces that govern their interactions. Several comprehensive pedagogical treatments
620 of the SM already exist in the literature [3–8] and this section will not rehash those. Rather, this section
621 presents a brief overview of the SM particles and forces in order to define them for subsequent discussions.

622 The Standard Model consists of two primary categories of fundamental particles: fermions (spin 1/2
 623 particles) and bosons (integer spin particles). The SM also describes three forces: electromagnetism, the
 624 weak nuclear force, and the strong nuclear force. Gravity is not included in the theory and is largely irrel-
 625 evant at the scales currently probed by collider experiments. Within the fermions, there are both quarks
 626 (which interact via all three forces) and leptons. The charged leptons interact via electromagnetic and weak
 627 interactions, while neutrinos (neutral leptons) interact only via the weak force. Within the bosons, there
 628 are the W^\pm and Z bosons (the mediators of the weak force), the gluon (g , the mediator of the strong
 629 force), and the photon (γ , the mediator of the electromagnetic force). Finally, there is the Higgs boson,
 630 a fundamental spin zero particle resulting from the Higgs mechanism of electroweak symmetry breaking.

631 Figure 1.1 summarizes the fermions and bosons of the SM.

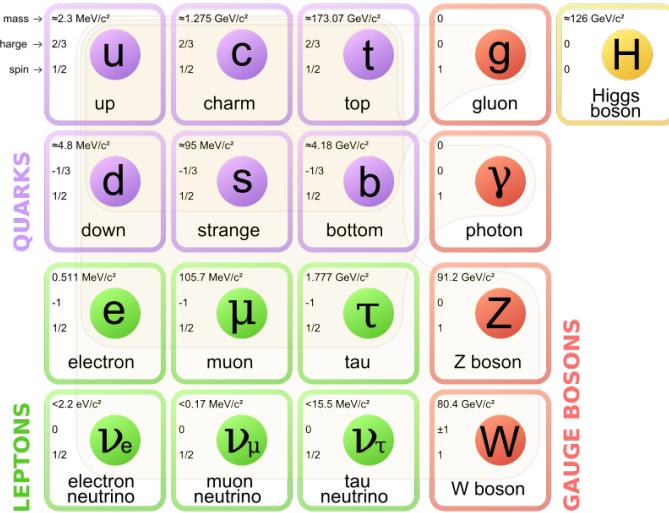

Figure 1.1: The particles of the Standard Model and their properties [6].

632 The Standard Model coalesced into a unified theoretical framework in the 1960s through the work
 633 of Glashow, Weinberg, Salam, and others on the theory of electroweak interactions [9–12]. This theory
 634 characterized both the electromagnetic and weak interactions as unified under a single gauge symmetry
 635 group, namely $SU(2) \times U(1)$. At low enough energy scales (on the order of the W and Z masses), the
 636 electroweak symmetry is broken, as evidenced by the fact that the weak bosons have mass while the photon
 637 does not. The discovery of the Higgs boson in 2012 confirmed the Higgs mechanism as the most likely
 638 candidate for this electroweak symmetry breaking [1, 2]. The complete SM consists of this electroweak

639 theory combined with the theory of quantum chromodynamics (which models the strong sector as a non-
640 Abelian $SU(3)$ gauge group)¹.

641 **I.2 ELECTROWEAK SYMMETRY BREAKING AND THE HIGGS**

642 In the Standard Model Lagrangian, it is difficult to include mass terms for the W and Z bosons without
643 breaking the fundamental gauge symmetry of the Lagrangian. A traditional mass term does not preserve
644 the $SU(2) \times U(1)$ symmetry. Additionally, scattering of massive W and Z bosons violate unitarity and
645 these diagrams diverge at high energy scales. In the 1960s, Higgs, Brout, Englert, Guralnik, Kibble, and
646 Hagen developed a mechanism for spontaneous symmetry breaking via the addition of a complex scalar
647 doublet to the SM. Three of the four real degrees of freedom of this complex field would go to the lon-
648 gitudinal modes of the W^\pm and Z , thus allowing them to have mass [14–17]. The remaining degree of
649 freedom would manifest as an additional scalar, known now as the Higgs boson.

650 The mechanism works by introducing a Lagrangian for the newly introduced field that still respects the
651 symmetry of the Standard Model inherently, but with a minimum at a non-zero vacuum expectation value
652 for the field. In this minimum of the potential, the electroweak symmetry is broken. Specifically, consider
653 a complex scalar doublet Φ with four degrees of freedom, as shown in equation I.1.

$$\Phi = \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} \phi_1^+ + i\phi_2^+ \\ \phi_1^0 + i\phi_2^0 \end{pmatrix} \quad (\text{I.1})$$

654 The simplest potential of a self-interacting Higgs that still respects the SM symmetry is given in equa-
655 tion I.2.

$$V(\Phi) = \mu^2 \Phi^\dagger \Phi + \lambda (\Phi^\dagger \Phi)^2 \quad (\text{I.2})$$

656 If the μ^2 term of this potential is positive, then the potential has a minimum at $\Phi = 0$ and the electroweak

¹For a pedagogical treatment of the physics of quantum chromodynamics, see reference [13].

⁶⁵⁷ symmetry is preserved. However, if instead $\mu^2 < 0$, then the minimum is at a finite value of Φ , namely

$$\Phi_{\min} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix} \quad (1.3)$$

⁶⁵⁸ where $v = \sqrt{\mu^2/\lambda}$. Because this is the location of the minimum, it corresponds to the vacuum expecta-
⁶⁵⁹ tion value for the field ($\langle \Phi \rangle = \Phi_{\min}$). The excitations of the Higgs can then be parameterized as

$$\Phi = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v + H \end{pmatrix} \quad (1.4)$$

⁶⁶⁰ The full scalar Lagrangian, including the kinetic term, is then given as

$$\mathcal{L}_s = (D^\mu \Phi)^\dagger (D_\mu \Phi) - V(\Phi) \quad (1.5)$$

⁶⁶¹ where the covariant derivative is defined as

$$D_\mu = \partial_\mu + \frac{ig}{2} \tau^a W_\mu^a + ig' Y B_\mu \quad (1.6)$$

⁶⁶² and W^1, W^2, W^3 and B are the $SU(2)$ and $U(1)$ gauge fields of the electroweak theory, respectively. g
⁶⁶³ and g' are the corresponding coupling constants. The Pauli matrices are represented with τ . With the
⁶⁶⁴ scalar Lagrangian in place, the physical gauge fields can then be written as

$$W_\mu^\pm = \frac{1}{\sqrt{2}} (W_\mu^1 \mp i W_\mu^2) \quad (1.7)$$

⁶⁶⁵

$$Z_\mu = \frac{-g' B_\mu + g W_\mu^3}{\sqrt{g^2 + g'^2}} \quad (1.8)$$

⁶⁶⁶

$$A_\mu = \frac{g B_\mu + g' W_\mu^3}{\sqrt{g^2 + g'^2}} \quad (1.9)$$

⁶⁶⁷ Equation 1.7 corresponds to the charged W^+ and W^- bosons, equation 1.8 corresponds to the neutral Z
⁶⁶⁸ boson, and equation 1.9 corresponds to the neutral photon. The masses of the particles also arise from the
⁶⁶⁹ Lagrangian. The photon has zero mass, while the masses of the W and Z bosons are given in equation 1.10.

⁶⁷⁰

$$\begin{aligned} M_W^2 &= \frac{1}{4}g^2v^2 \\ M_Z^2 &= \frac{1}{4}(g^2 + g'^2)v^2 \end{aligned} \quad (1.10)$$

⁶⁷¹ The fermion masses also arise through a coupling with the Higgs via the Yukawa interaction (for a detailed
⁶⁷² description, see [8]). In this case the coupling between the Higgs and the fermions goes as

$$g_{h\bar{f}f} = \frac{m_f}{v} \quad (1.11)$$

⁶⁷³ The full Lagrangian of Higgs interactions can be written as

$$\mathcal{L}_{\text{Higgs}} = -g_{h\bar{f}f}\bar{f}fh + \frac{g_{hhh}}{6}h^3 + \frac{g_{hhhh}}{24}h^4 + \delta_V V_\mu V^\mu \left(g_{hVV}H + \frac{g_{hhVV}}{2}h^2 \right) \quad (1.12)$$

⁶⁷⁴ with

$$\begin{aligned} g_{hVV} &= \frac{2m_V^2}{v} & g_{hhVV} &= \frac{2m_V^2}{v^2} \\ g_{hhh} &= \frac{3m_h^2}{v} & g_{hhHH} &= \frac{3m_h^2}{v^2} \end{aligned} \quad (1.13)$$

⁶⁷⁵ The last term of the Lagrangian appears twice, once for W bosons and once for Z bosons. V refers to
⁶⁷⁶ the W^\pm and Z , and $\delta_W = 1$ while $\delta_Z = 1/2$. Phenomenologically, there are a few features of this
⁶⁷⁷ Lagrangian that are useful to note. First, note that the Higgs mass is a free parameter of the theory that
⁶⁷⁸ must be determined experimentally. Second, note that the coupling of the Higgs to the vector bosons and
⁶⁷⁹ fermions scales as a function of the masses of these particles, a fact that is important when considering
⁶⁸⁰ both the production and decays of the Higgs. Finally, note the presence of the cubic and quartic Higgs self
⁶⁸¹ interaction terms, which can lead to final states with multiple Higgs bosons produced.

682 1.3 HIGGS BOSON PRODUCTION AND DECAY

683 This section discusses the properties of Higgs production and decay mechanisms. The details presented
684 here will focus on the properties of a 125 GeV Higgs boson, as this is the mass closest to that of the newly
685 discovered Higgs.

686 1.3.1 HIGGS PRODUCTION

687 The Higgs is produced by four main production modes at the Large Hadron Collider - gluon-gluon fusion
688 (ggF), vector boson fusion (VBF), associated production with a W or Z boson, or associated production
689 with top quarks ($t\bar{t}H$). Figure 1.2 shows the Feynman diagrams for these four modes.

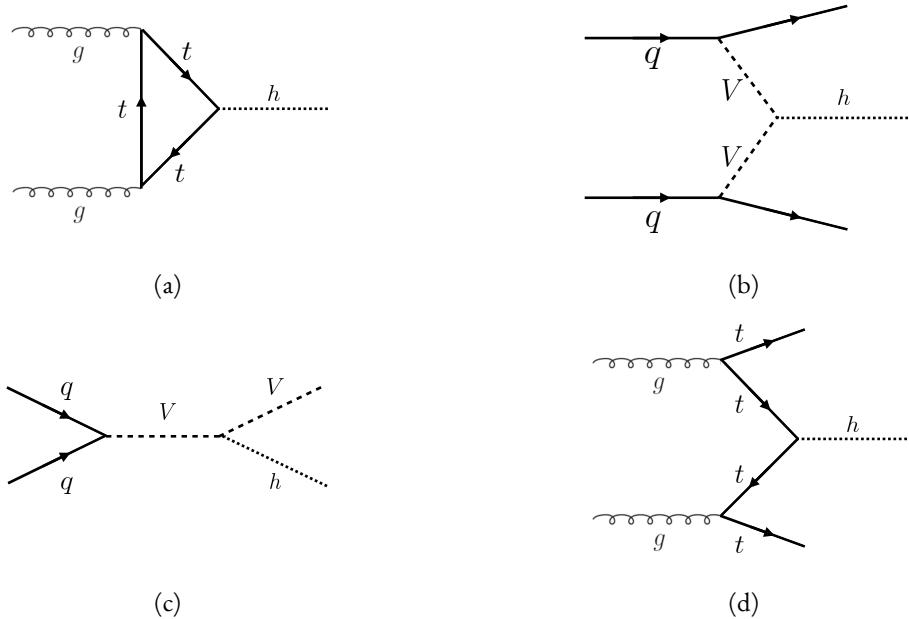

Figure 1.2: The four most common Higgs boson production modes at the LHC: (a) gluon-gluon fusion, (b) vector boson fusion, (c) $W/Z + H$ production, (d) $t\bar{t}H$ production

690 In gluon-gluon fusion, gluons from the incoming protons fuse via a top-quark loop to produce a Higgs.
691 The top quark is the dominant contribution in the loop due to its heavy mass and the fact that the Higgs-
692 fermion coupling constant scales with fermion mass. In vector boson fusion, the incoming quarks each
693 radiate a W or Z boson which fuse to produce the Higgs. This production mode results in a final state
694 with a Higgs boson and two additional jets which tend to be forward because they carry the longitudinal

695 momentum of the incoming partons. The Higgs can also be produced in association with a W or Z boson.
 696 The W/Z is produced normally and then radiates a Higgs². Finally, the Higgs can be produced in associa-
 697 tion with two top quarks. Each incoming gluon splits into a $t\bar{t}$ pair, and one of the top pairs combines to
 698 create a Higgs. Figure 1.3 shows the production cross section for a 125 GeV Higgs boson in each of these
 modes at a pp collider as a function of center of mass energy. In figure 1.3, note that gluon fusion has the

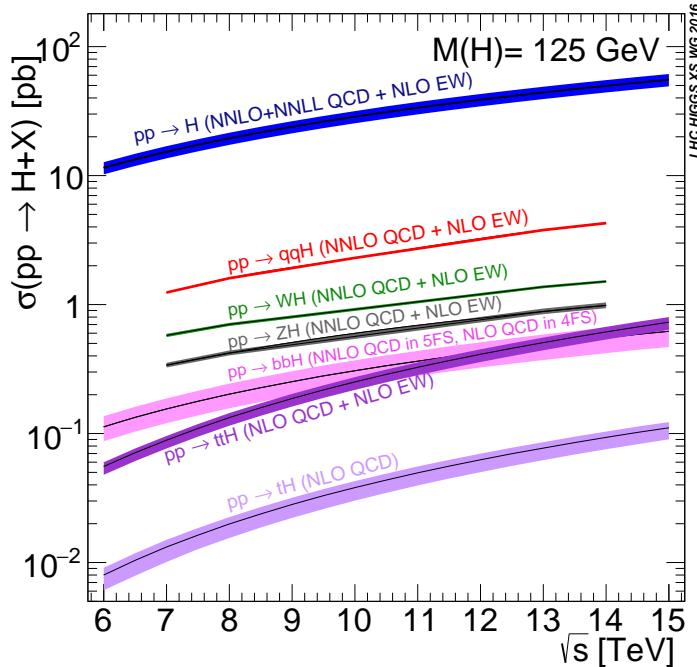

Figure 1.3: Higgs production cross sections as a function of center of mass energy (\sqrt{s}) at a pp collider [18].

699
 700 largest cross section, while VBF is the second largest at approximately a factor of 10 smaller. The figure also
 701 includes the less commonly studied $b\bar{b}H$ and tH modes. While the $b\bar{b}H$ mode has a larger cross section
 702 than $t\bar{t}H$, it also has larger backgrounds and is thus less sensitive. The tH mode is not as sensitive as $t\bar{t}H$
 703 due to its lower cross section. At $\sqrt{s} = 8$ TeV, ggF production of a 125 GeV Higgs has a cross section
 704 of $19.47^{+1.54}_{-1.67}$ pb, while VBF has a cross section of $1.601^{+0.036}_{-0.035}$ pb [18]. Both the gluon fusion and vector
 705 boson fusion cross sections have been computed to next-to-next-to-leading order (NNLO) in the QCD
 706 couplings and next-to-leading order in the electroweak couplings [19–26]. The gluon fusion cross section
 707 also includes next-to-next-to-leading logarithm (NNLL) resummation [27]. The cross sections of all of

²This mode is also sometimes known as “Higgs-strahlung”.

708 the main Higgs production modes at this center of mass energy, as well as their uncertainties from varying
 709 the QCD renormalization and factorization scales and PDFs, are summarized in table 1.1 for a 125 GeV
 710 Higgs. The relative uncertainty of the gluon fusion mode is larger than the relative uncertainty in the
 711 vector boson fusion mode due to the fact that gluon fusion production happens through a loop.

Production mode	σ (pb)	QCD scale uncert. (%)	PDF + α_s uncert. (%)
Gluon fusion	19.47	+7.3 / - 8.0	3.1
Vector boson fusion	1.601	+0.3 / - 0.2	2.2
WH	0.7026	+0.6 / - 0.9	2.0
ZH	0.4208	+2.9 / - 2.4	1.7
bbH	0.2021	+20.7 / - 22.3	
$t\bar{t}H$	0.1330	+4.1 / - 9.2	4.3
tH (t -channel)	0.01869	+7.3 / - 16.5	4.6
tH (s -channel)	1.214×10^{-3}	+2.8 / - 2.4	2.8

Table 1.1: Production cross sections for a 125 GeV Higgs boson at $\sqrt{s} = 8$ TeV with scale and PDF uncertainties [18].

712 1.3.2 HIGGS BRANCHING RATIOS

713 The fact that the Higgs couples more strongly to more massive particles is crucial for understanding its
 714 branching ratios. The width for Higgs decays to fermions is given by equation 1.14 [5].

$$\Gamma(H \rightarrow f\bar{f}) = \frac{N_c \sqrt{2} G_F m_f^2 m_H}{8\pi} \quad (1.14)$$

715 In this case, N_c is the number of colors, G_F is the Fermi constant, m_f is the mass of the fermion, and
 716 m_H is the mass of the Higgs. Note that the width scales with the square of the fermion mass. (This also
 717 assumes that the Higgs mass is large enough to decay with both the fermions on shell.)

718 The decay width to WW , in the case where both W bosons are produced on shell ($m_H \geq 2m_W$), is
 719 given in equation 1.15 [5].

$$\Gamma(H \rightarrow W^+ W^-) = \frac{\sqrt{2} G_F M_W^2 m_H}{16\pi} \frac{\sqrt{1-x_W}}{x_W} (3x_W^2 - 4x_W + 4) \quad (1.15)$$

720 where m_W is the mass of the W and $x_W = 4M_W^2/m_H^2$. To get the branching ratio to ZZ (in the regime
 721 where $m_H \geq 2m_Z$), the equation is divided by 2 to account for identical particles in the final state, and
 722 x_W is replaced with $x_Z = 4M_Z^2/m_H^2$. This is shown in equation 1.16 [5].

$$\Gamma(H \rightarrow ZZ) = \frac{\sqrt{2}G_F M_Z^2 m_H}{32\pi} \frac{\sqrt{1-x_Z}}{x_Z} (3x_Z^2 - 4x_Z + 4) \quad (1.16)$$

723 The more general formula for Higgs branching into WW or ZZ , taking into account the case where one
 724 or both vector bosons is off-shell, is shown in equation 1.17 [28].

$$\Gamma(H \rightarrow V^*V^*) = \frac{1}{\pi^2} \int_0^{M_H^2} \frac{dq_1^2 M_V \Gamma_V}{(q_1^2 - M_V^2)^2 + M_V^2 \Gamma_V^2} \int_0^{(M_H - q_1)^2} \frac{dq_2^2 M_V \Gamma_V}{(q_2^2 - M_V^2)^2 + M_V^2 \Gamma_V^2} \Gamma_0 \quad (1.17)$$

725 Here, q_1^2 and q_2^2 are the invariant masses of the virtual gauge bosons, M_V is the W or Z mass, and Γ_V is
 726 the W or Z width. Γ_0 is the squared matrix element, which is given in equation 1.18 [28].

$$\Gamma_0 = \frac{G_F M_H^3}{8\sqrt{2}\pi} \delta_V \sqrt{\lambda(q_1^2, q_2^2, M_H^2)} \left[\lambda(q_1^2, q_2^2, M_H^2) + \frac{12q_1^2 q_2^2}{M_H^4} \right] \quad (1.18)$$

727 The function λ is defined as $\lambda(x, y, z) = (1 - x/z - y/z)^2 - 4xy/z^2$. The integral in the general
 728 off-shell boson case is much more difficult to interpret than the simpler on-shell branching ratios, but it
 729 can be evaluated numerically. These branching ratio formulas can also be visualized as a function of Higgs
 730 mass, as shown in figure 1.4. There are a few interesting features to note in this figure. First, note that at
 731 high Higgs masses, once on-shell production of both W and Z bosons is possible, these two decays are
 732 dominant due to the large masses of the W/Z . Also note that the branching ratio to W s is twice that of
 733 Z s at these large masses due to the fact that there are two charged W bosons (W^\pm) and only one Z boson³.
 734 At 125 GeV, the Higgs is accessible through many different decay modes. The largest branching ratio is
 735 the decay $H \rightarrow b\bar{b}$ at 58.24% [18]. This branching is larger than the WW/ZZ decays because one of
 736 the two bosons must be produced off-shell for $m_h = 125$ GeV. The second largest branching ratio is
 737 to WW^* at 21.37 % (before taking into account the branching ratios of the W). Table 1.2 summarizes

³In the Higgs Lagrangian, this extra symmetry factor is quantified by the δ_V noted in equation 1.12.

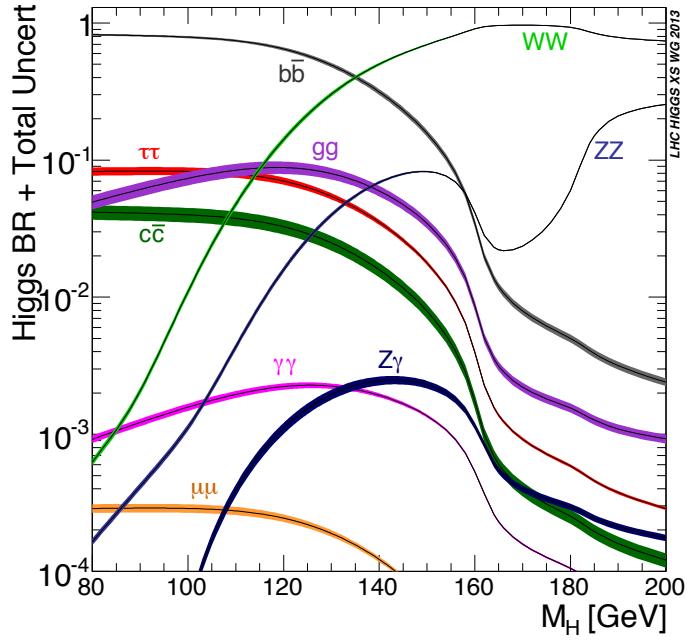

Figure 1.4: Higgs boson branching ratios as a function of m_H [18].

738 the theoretical branching ratios for a Higgs with a mass of 125 GeV. Note that there is a Higgs branching
 739 ratio to $\gamma\gamma$ even though photons are massless. This decay happens through a loop, which suppresses the
 740 branching ratio⁴.

Decay	Branching ratio (%)	Relative uncertainty (%)
bb	58.24	+0.25 / -0.25
WW^*	21.37	+0.99 / -0.99
gg	8.187	+3.40 / -3.41
$\tau\tau$	6.272	+1.17 / -1.16
cc	2.891	+1.20 / -1.20
ZZ^*	2.619	+0.99 / -0.99
$\gamma\gamma$	0.2270	+1.73 / -1.72
$Z\gamma$	0.1533	+5.71 / -5.71
$\mu\mu$	0.02176	+1.23 / -1.23

Table 1.2: Theoretical branching ratios for a 125 GeV Higgs boson, quoted as a percentage of the total width of the Higgs. Uncertainties shown are relative to the branching ratio value [18].

741 Note that the branching ratios alone do not tell the full story of which Higgs channels are the most

⁴The largest contributions to the loop are the top quark and W boson.

742 sensitive. For example, the $H \rightarrow b\bar{b}$ channel in gluon fusion production is incredibly difficult to observe
 743 due to the large QCD dijet background at the LHC. However, in associated production of the Higgs,
 744 where a W or Z gives additional final state particles that can be used to reduce background, a search for
 745 $H \rightarrow b\bar{b}$ can be sensitive. The combinations of production and decay modes that are most commonly
 746 studied at the LHC are summarized in table 1.3 [5].

Decay	Inclusive (incl. ggF)	VBF	WH/ZH	$t\bar{t}H$
$H \rightarrow \gamma\gamma$	✓	✓	✓	✓
$H \rightarrow b\bar{b}$			✓	✓
$H \rightarrow \tau^+\tau^-$		✓		
$H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$	✓	✓	✓	
$H \rightarrow ZZ \rightarrow 4\ell$	✓			
$H \rightarrow Z\gamma \rightarrow \ell\ell\gamma$	very low			

Table 1.3: Possible channels for Higgs searches. Checkmarks denote the most sensitive production modes for each decay channel [5].

747 1.4 HIGGS PAIR PRODUCTION IN THE STANDARD MODEL

748 The Standard Model also allows for processes that produce two Higgs bosons in the final state, known
 749 as Higgs pair production or di-Higgs production. The two main production mechanisms are shown in
 figure 1.5. The two diagrams in figure 1.5 interfere destructively with one another, resulting in a low overall

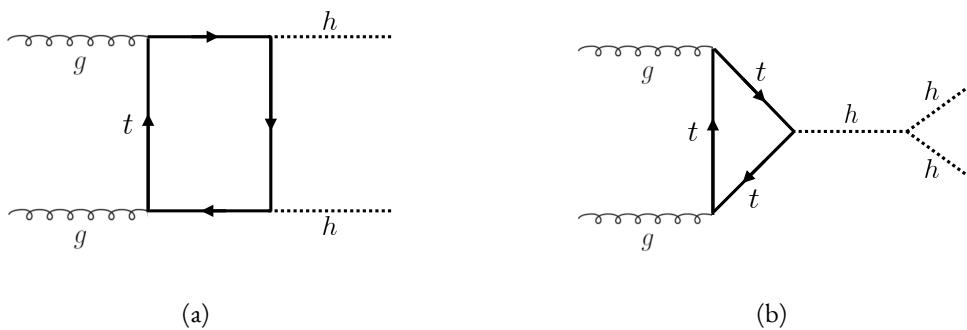

Figure 1.5: The two leading diagrams for Standard Model di-Higgs production at the LHC: (a) box diagram, (b) Higgs self coupling.

750
 751 cross section for di-Higgs production at the LHC. Nevertheless, Higgs pair production is quite interesting

752 to study because it gives direct access to the λ parameter of the Higgs potential, also known as the Higgs
753 self coupling. The diagram in figure 1.5(b) is sensitive to this coupling through the triple Higgs vertex.

754 One can substitute the gluon fusion production of diagram 1.5(b) with any of the other production
755 modes previously discussed. These other modes do not suffer from interference with the box diagram in
756 figure 1.5(a) due to the presence of additional particles in the final state. They still have a lower cross section
757 than the gluon fusion mode, however. The cross sections for di-Higgs production in the different modes,
758 as well as their uncertainties, are shown in table 1.4 [29]. These are shown for $\sqrt{s} = 14$ TeV as this is the
759 expected center of mass energy for the High Luminosity LHC and this energy is more sensitive to di-Higgs
production. Note that the scale of cross section quoted is now in fb rather than pb.

Production mode	σ (fb)	Total uncert. (%)
Gluon fusion	33.89	+37.2 / - 27.8
Vector boson fusion	2.01	+7.6 / - 5.1
$W H H$	0.57	+3.7 / - 3.3
$Z H H$	0.42	+7.0 / - 5.5
$t \bar{t} H$	1.02	-

Table 1.4: Production cross sections for pair production of a 125 GeV Higgs boson at $\sqrt{s} = 14$ TeV with total uncertainty [29]. The uncertainties include QCD scale and PDF variations as well as uncertainties on α_S .

760

761 1.5 HIGGS PAIR PRODUCTION IN THEORIES BEYOND THE STANDARD MODEL

762 The Higgs pair production cross section in the Standard Model is rather small, and datasets on the scale of
763 the full 3000 fb^{-1} expected from the High Luminosity LHC will be required to obtain sensitive measure-
764 ments of the Higgs self-coupling [29]. However, the discovery of the Higgs also gives particle physicists
765 a new tool that can be exploited in the search for new physics beyond the Standard Model. In particular,
766 Higgs pair production is a promising channel in the search for new physics. The cross section for di-Higgs
767 production can be altered through both resonant and non-resonant production of Higgs pairs. In non-
768 resonant production, di-Higgs production vertices can arise from the presence of a new strong sector and
769 additional colored particles [30–32]. Figure 1.6 shows examples of the types of vertices that can arise. In
770 the resonant case, new heavy particle can decay to Higgs pairs. Such new particles can include heavy Higgs

771 bosons arising in two Higgs doublet models (2HDM) or Higgs portal models as well as heavy gravitons in
 772 Randall-Sundrum theories [30, 33–39]. Figure 1.7 shows a generic diagram for a heavy resonance decaying
 773 to two Higgs bosons. In the 2HDM, X corresponds to the heavy CP-even scalar H . In the Randall-
 Sundrum model, X corresponds to a heavy spin-2 graviton G_{KK}^* . The next sections provide more detail

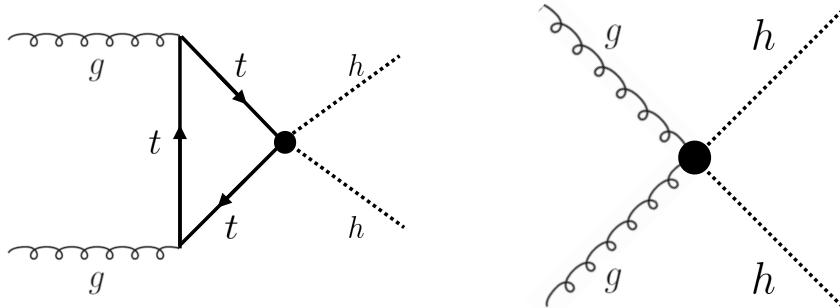

Figure 1.6: Diagrams with new vertices for non-resonant Higgs pair production arising in composite Higgs models.

774
 775 on the phenomenology of resonant Higgs production in Randall-Sundrum and 2HDM models, as these
 models will later be tested in a dedicated search for resonant production of boosted Higgs pairs.

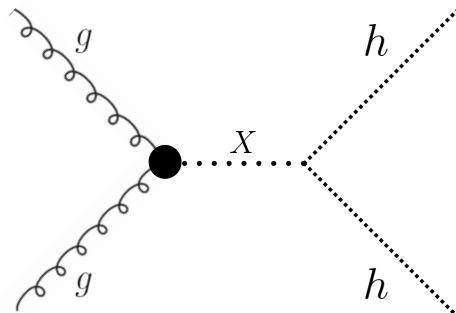

Figure 1.7: Generic Feynman diagram for resonant Higgs pair production in BSM theories.

776

777 1.5.1 RANDALL-SUNDRUM GRAVITONS

778 The Randall-Sundrum model is a proposed solution to the hierarchy problem that posits a five-dimensional
 779 warped spacetime that contains two branes: one where the force of gravity is very strong and a second brane
 780 at the TeV scale corresponding to the known Standard Model sector [33]. In the theory, the branes are

781 weakly coupled and the graviton probability function drops exponentially going from the gravity brane
 782 to the SM brane, rendering gravity weak on the SM brane. The experimental consequence of this theory
 783 is a tower of widely spaced (in mass) Kaluza-Klein graviton resonances. In theories where the fermions
 784 are localized to the SM brane, production of gravitons from fermion pairs is suppressed and the primary
 785 mode of production is gluon fusion [34]. These gravitons have a substantial branching fraction to Higgs
 786 pairs, ranging from 6.43% for gravitons with a mass of 500 GeV to 7.66% at 3 TeV. Figure 1.8 shows the
 787 branching ratios of the spin-2 Randall Sundrum graviton (RSG) as a function of its mass. The predomi-
 788 nant decays are to $t\bar{t}$ above the mass threshold for that channel.

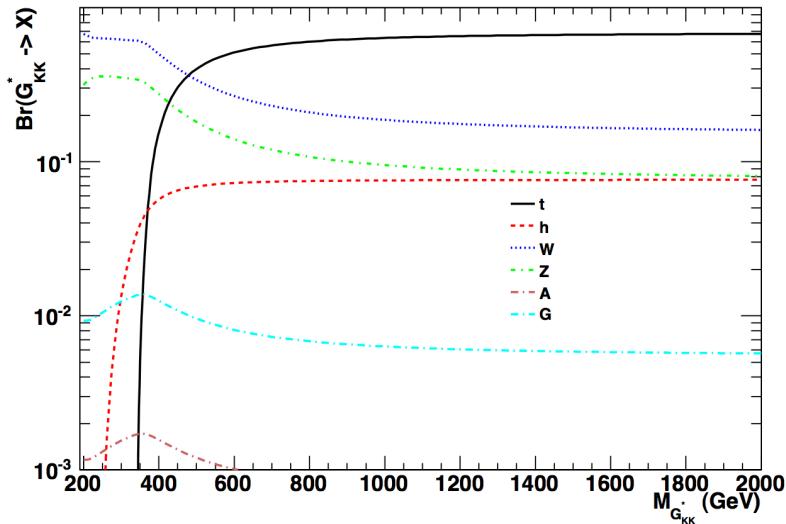

Figure 1.8: Branching ratios for a spin-2 Randall-Sundrum graviton as a function of mass computed in MadGraph with the CP3-Origins implementation [34, 40, 41].

789 Randall-Sundrum models have two free parameters - the mass of the graviton and a curvature parameter
 790 k . Typically, rather than k , the theory is parameterized using $c \equiv k/\bar{M}_{\text{pl}}$, where \bar{M}_{pl} is the reduced
 791 Planck mass. The cross section for production of the RSG decreases as a function of mass and is strongly
 792 dependent on the gluon PDF. The increase in center of mass energy from 8 to 13 TeV in LHC Run 2
 793 greatly increases the cross section at higher mass. Figure 1.9 shows the cross section as a function of graviton
 794 mass at $\sqrt{s} = 13$ TeV for RSG models with $c = 1.0$ and $c = 2.0$.

795 Another interesting feature of the theory is that the width of the graviton increases with both c and
 796 $m_{G_{\text{KK}}^*}$. Figure 1.10 shows the graviton width for both $c = 1.0$ and $c = 2.0$ as a function of mass. In

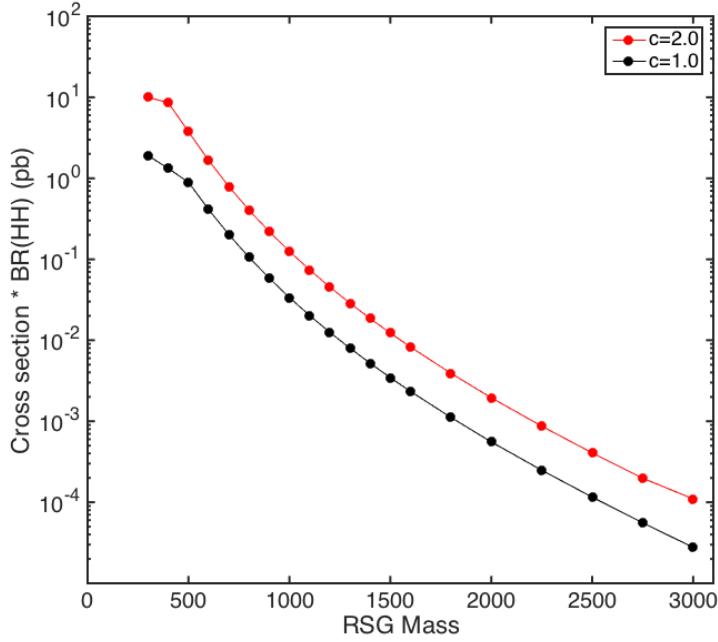

Figure 1.9: $\sigma \times \text{BR}(HH)$ for Randall-Sundrum gravitons as a function of mass computed in MadGraph with the CP3-Origins implementation [34, 40, 41].

797 $c = 1.0$, the width starts at 8.365 GeV for a mass of 300 GeV and increases to 187.2 GeV at a mass of
 798 3 TeV. Similarly, with $c = 2.0$, the width starts at 33.46 GeV for $m_G = 300$ GeV and increases to
 799 748.8 GeV at a mass of 3 TeV.

800 1.5.2 Two Higgs Doublet Models

801 In Two Higgs Doublet Models (2HDM), a second complex scalar doublet is added to the Standard Model [36–
 802 38]. In this case, all four degrees of freedom in the second doublet correspond to new particles, meaning
 803 that there are five total scalars from the two Higgs doublets - h (light CP-even Higgs), H (heavy CP-even
 804 Higgs), A (heavy CP-odd Higgs), and H^\pm (charged Higgs). The model is parameterized by two main pa-
 805 rameters. The first, $\tan \beta \equiv \frac{v_2}{v_1}$, is the ratio of the vacuum expectation values of the two Higgs doublets
 806 (where v_1 corresponds to the v in the SM Higgs model described above). The second parameter is α , a mix-
 807 ing angle between the heavy and light Higgs fields. Models are also often parameterized with $\cos(\beta - \alpha)$
 808 rather than α directly. The limit where $\cos(\beta - \alpha) = 0$ is called the alignment limit, and in this limit the

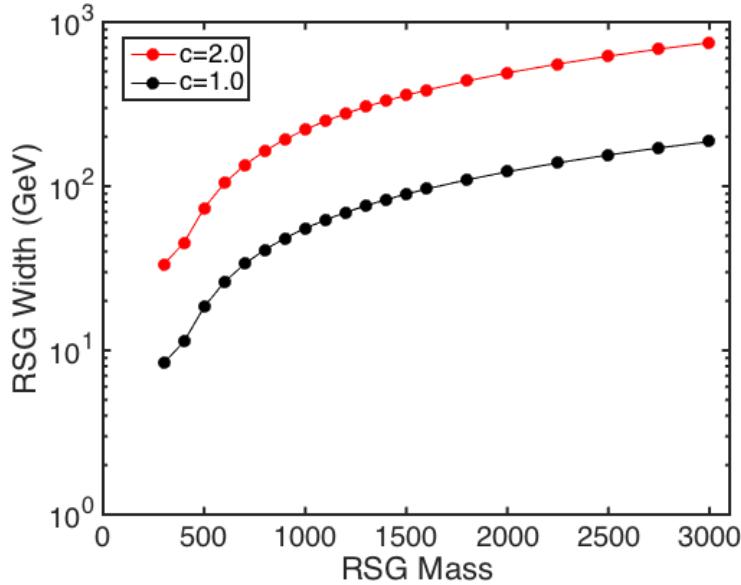

Figure 1.10: Randall-Sundrum graviton width as a function of mass computed in MadGraph with the CP3-Origins implementation [34, 40, 41]

809 light Higgs h has the same couplings as a Standard Model Higgs. Measurements of the Higgs boson have
 810 put constraints on these two parameters, but near the alignment limit there is still much unprobed phase
 811 space depending on the exact models and values of $\tan \beta$ being considered [42].

812 2HDM models are usually separated into two main types - Type I and Type II. In Type I models, the
 813 charged fermions only couple to the second Higgs doublet, leading to a fermiophobic light Higgs. In
 814 Type II models, up-type quarks couple to the first doublet while down-type quarks couple to the second
 815 doublet. One specific realization of a Type II 2HDM is the Minimal Supersymmetric Standard Model
 816 (MSSM).

817 Resonant di-Higgs production in 2HDM models can proceed through decays of the heavy CP-even
 818 Higgs $H \rightarrow hh$. The branching ratio for $H \rightarrow hh$ depends on the model type as well as the values of
 819 $\tan \beta$ and $\cos \beta - \alpha$. Figure 1.11 shows the branching ratios as a function of the mass of the heavy scalar
 820 H for both Type I and Type II models. Depending on the type of model hh can be a substantial fraction
 821 of the decays of H .

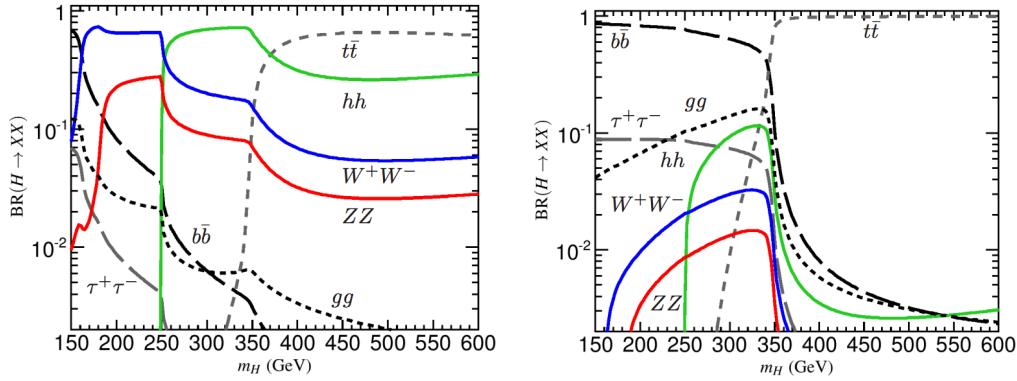

Figure 1.II: Branching ratios for heavy Higgs H in Type I (left) and Type II (right) 2HDM models with $\tan \beta = 1.5$ and $\cos(\beta - \alpha) = 0.1$ (0.01) for Type I (Type II) [38].

822 1.6 CONCLUSION

823 Studying the Higgs sector is essential for understanding the details of how mass arises in the Standard
 824 Model and how the electroweak symmetry is broken. The discovery of the Higgs boson also opens the
 825 door for its use as a tool to search for new physics, and Higgs pair production is an ideal candidate for
 826 this study. Even if no BSM physics is found in Higgs pair production, searches for Higgs pairs will put
 827 constraints on the Higgs self coupling and thus improve knowledge of the Standard Model and the details
 828 of the Higgs potential.

*The enthusiasm and motivation to explore particle physics
at the high-energy frontier knows no borders between the
nations and regions of the planet.*

The ATLAS detector and the Large Hadron 831 Collider

832

This chapter presents an overview of the experimental systems used to conduct the measurements in this thesis. First, a brief overview of the accelerator, the Large Hadron Collider, will be given. In this section, the accelerator conditions relevant to data-taking are presented as well. Next, an overview of the ATLAS experiment is given. The basics of each sub-detector's role are summarized, as well as the details of the datasets accumulated. Then, a brief interlude on the ATLAS Muon New Small Wheel upgrade is presented. While this new detector does not have a direct impact on any of the datasets recorded so far, it will have an impact on future analyses and the work done on it is briefly summarized here. Finally, an overview of object reconstruction in ATLAS is given. While the details of all of the algorithms will not be presented in detail, aspects of the reconstruction performance are shown as these are relevant to the results presented later in this thesis.

842 2.1 THE LARGE HADRON COLLIDER

843 The Large Hadron Collider (LHC) is a proton-proton collider at the CERN laboratory in Geneva, Switzer-
844 land [43]. It was designed for a maximum collision center of mass energy of $\sqrt{s} = 14 \text{ TeV}$ and has a
845 circumference of 26.7 kilometers. Four main experiments are located at the interaction points (IP) of
846 the accelerator: ATLAS (A Toroidal LHC ApparatuS), CMS (the Compact Muon Solenoid), ALICE (A
847 Large Ion Collider Experiment), and LHCb [44–47]. Figure 2.1 shows a schematic of the LHC ring and
848 its experiments.

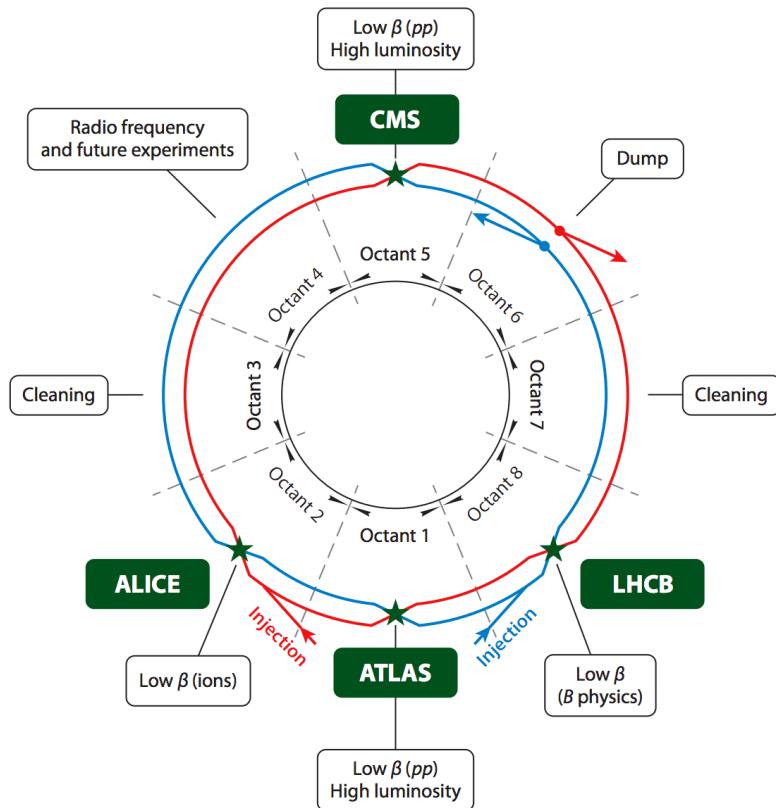

Figure 2.1: A schematic view of the LHC ring [48]. Four main experiments are located at interaction points along the ring. ATLAS and CMS are general purpose experiments, while ALICE is dedicated to heavy ion collisions and LHCb is dedicated to studying B physics.

849 One of the most interesting features of the LHC is its magnet design. Because the tunnel does not have
850 room for separate superconducting magnets for each of the beam pipes, the LHC employs a twin-bore
851 magnet design. Each magnet must hold an 8.3 Tesla magnetic field in order to bend the proton beams at

852 $\sqrt{s} = 14$ TeV. The superconducting magnets are cooled to a temperature of 1.9 Kelvin with superfluid
 853 helium.

854 2.1.1 INSTANTANEOUS LUMINOSITY

855 The rate of physics events expected from the accelerator is dependent on the instantaneous luminosity
 856 of the machine and the cross section of the physics process, $R_{\text{events}} = L\sigma$. Here, R_{events} is the num-
 857 ber of events per second, L is the instantaneous luminosity of the machine, and σ is the cross section for
 858 the physics process being measured. The instantaneous luminosity of the LHC is determined by numer-
 859 ous factors related to beam conditions. Equation 2.1 gives the equation for instantaneous luminosity of a
 860 Gaussian beam profile [48].

$$L = \frac{N_b^2 n_b f_{\text{rev}} \gamma_r}{4\pi \epsilon_n \beta^*} F \quad (2.1)$$

861 The LHC collides protons in bunches, and in the above equation N_b is the number of protons per bunch
 862 while n_b is the number of bunches per beam. Nominally, the LHC can hold up to 2808 proton bunches.
 863 f_{rev} is the revolution frequency. ϵ_n is the normalized transverse beam emittance, a measurement of the
 864 average spread of the particles in position-momentum space which has the dimension of length. β^* is the
 865 value of the β function for the beam at the interaction point. It relates the emittance to the Gaussian
 866 width of the beam with $\sigma_{\text{beam}} = \sqrt{\epsilon \cdot \beta}$. F is a reduction factor that corrects for the fact that the beams
 867 are colliding at an angle at the IP.

868 Another way of writing the instantaneous luminosity is shown in equation 2.2. In this case, the instan-
 869 taneous luminosity is written as the ratio of the rate of inelastic collisions to the inelastic cross section [49].

870

$$L = \frac{R_{\text{inel}}}{\sigma_{\text{inel}}} = \frac{\mu n_b f_{\text{rev}}}{\sigma_{\text{inel}}} \quad (2.2)$$

871 In this case, μ is the average number of interactions per bunch crossing in the accelerator. μ is a useful
 872 parameter for characterizing the amount of activity recorded in an experiment. As the instantaneous lu-
 873 minosity and thus μ increase, there are more interactions per bunch crossing and more activity is present
 874 in the detector. The level of activity is often characterized with $\langle \mu \rangle$, the measured per bunch crossing μ

875 value averaged over all bunch crossings. The interactions inside each bunch crossing that are not the main
 876 physics process of interest are often referred to as “pileup” interactions, and $\langle \mu \rangle$ is a measurement of the
 877 level of pileup in the detector.

878 2.1.2 EVOLUTION OF MACHINE CONDITIONS

879 This thesis uses datasets taken at three different center of mass energies: $\sqrt{s} = 7$ TeV data taken in the
 880 year 2011, $\sqrt{s} = 8$ TeV data taken in the year 2012, and $\sqrt{s} = 13$ TeV data taken in the year 2015. In
 881 addition to increasing center of mass energy, the instantaneous luminosity and parameters that determine
 882 it were evolving. Table 2.1 summarizes that machine conditions in each of these datasets.

	2011	2012	2015	Design
\sqrt{s} [TeV]	7	8	13	14
Number of bunches	1380	1380	1825	2808
Max. protons per bunch	1.45×10^{11}	1.7×10^{11}	1.2×10^{11}	1.15×10^{11}
Bunch spacing [ns]	50	50	25	25
Max. instantaneous luminosity [$\text{cm}^{-2}\text{s}^{-1}$]	3.7×10^{33}	7.7×10^{33}	5×10^{33}	10^{34}
β^* [m]	1.0	0.6	0.8	0.55
$\langle \mu \rangle$	11.6	20.7	13.7	-

Table 2.1: Evolution of LHC machine conditions [50, 51].

883 2.2 THE ATLAS DETECTOR

884 The ATLAS detector is the multi-purpose particle detector experiment located at the LHC’s Point 1 [44].
 885 It has nearly 4π coverage in solid angle around the interaction point. It consists of an inner detector for
 886 measuring charged particles, electromagnetic and hadronic calorimeters, and a muon spectrometer. Fig-
 887 ure 2.2 gives an overview of the detector.

888 2.2.1 COORDINATE SYSTEM

889 Before defining the properties of the individual detectors, it is important to establish the coordinate system
 890 used. Figure 2.3 shows a schematic of the coordinate system. The azimuthal plane (perpendicular to the

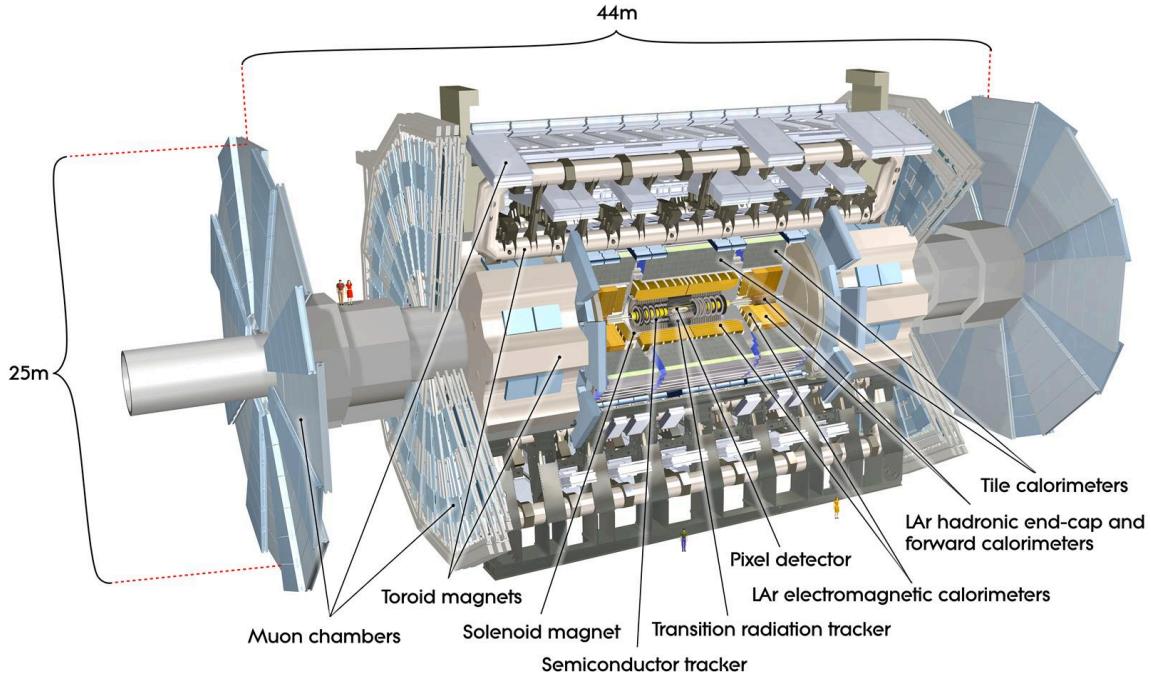

Figure 2.2: A full diagram of the ATLAS detector [44].

beam line) is defined as the x - y plane. The angle in this plane is referred to as ϕ . The angle relative to the beam axis is referred to as θ . Rather than using θ directly as a coordinate, the experiment often uses the pseudorapidity η , defined in equation 2.3.

$$\eta = -\ln \left(\tan \left(\frac{\theta}{2} \right) \right) \quad (2.3)$$

Pseudorapidity is the massless approximation of rapidity, the angle used to parameterize boosts in special relativity. This coordinate is useful in particle physics for two reasons. First, it means that differences in η are Lorentz invariant. Second, particle production is roughly constant in pseudorapidity. Particles with η close to zero are referred to as “central”, while those at high $|\eta|$ are called “forward”. In general, two main detector configurations can be seen in figure 2.2. There are “barrel” elements, which surround the beam line cylindrically and are in the central region of the detector. In the forward region, there are “endcap” regions which are arranged as disks perpendicular to the beam line.

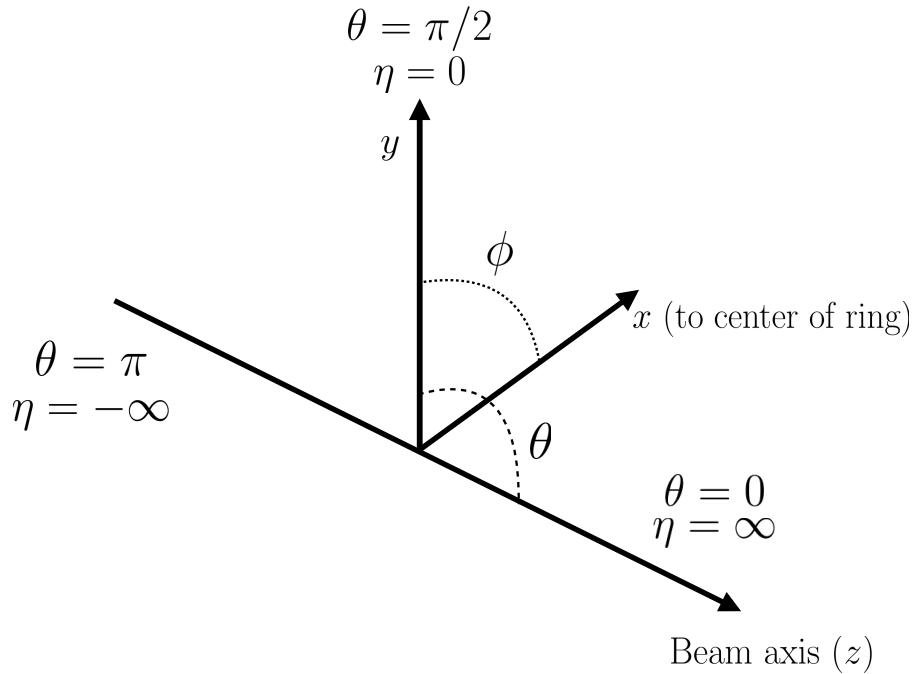

Figure 2.3: The ATLAS coordinate system. The z direction corresponds to the beam axis, while x and y define the transverse plane. θ is the angle relative to the beam axis and ϕ is the azimuthal angle. η , the pseudorapidity, approaches infinity at small angles relative to the beam axis.

901 2.2.2 INNER DETECTOR

902 The ATLAS Inner Detector (ID) system is built for precision tracking of charged particles. It covers the
 903 range $|\eta| < 2.5$. In this range, approximately 1000 particles are generated every bunch crossing in the de-
 904 tector [44]. This requires having fine granularity to achieve the resolutions required for good momentum
 905 measurement and vertex reconstruction.

906 The ID consists of three sub-components: the pixel detector, semiconductor tracker (SCT), and trans-
 907 sition radiation tracker (TRT). It is surrounded by a solenoid providing a 2 T axial magnetic field which
 908 bends particles in the transverse plane to allow for momentum measurement. Figure 2.4 shows the layout
 909 of each of these components.

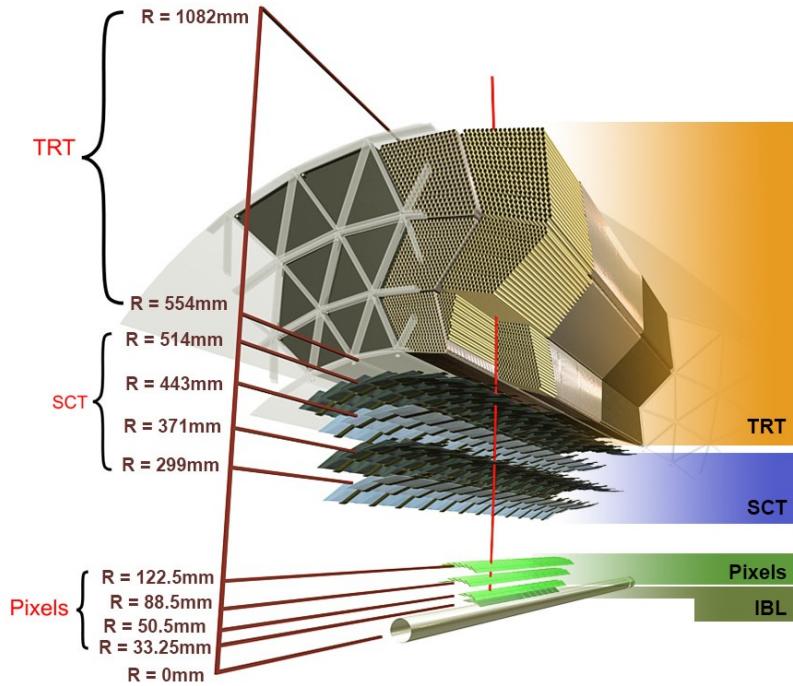

Figure 2.4: Layout of the ATLAS Inner Detector system [52].

910 PIXEL DETECTOR

911 The pixel detector is the first detector particles traverse after being generated in proton collisions and is
 912 the most granular detector. Its operation is crucial for precision tracking and vertex reconstruction as well
 913 as higher level object reconstruction like tagging of jets from b -quarks. The basic sensing element in this
 914 subdetector is a silicon pixel detector. The operating principle for the silicon pixels is that of a $p-n$ junction.
 915 When a charged particle passes through, it creates electron-hole pairs that are then separated by the electric
 916 field. The sensors are $250 \mu\text{m}$ thick and use oxygenated n -type wafers with readout pixels on the n^+ side
 917 of the detector [44]. Overall, the pixel detector has 1744 sensors and 80.4 million readout channels.

918 In the barrel region, the pixel detector has three concentric layers of sensors surrounding the beamline.
 919 In the endcap region, it consists of disks perpendicular to the beam axis. The detector is segmented in
 920 the $R-\phi$ plane and in z . Usually, three pixel layers are crossed by a charged particle track. The intrinsic
 921 accuracies of the sensors are $10 \mu\text{m}$ in $R-\phi$ and $115 \mu\text{m}$ in z (or R for the endcap).

922 **INSERTABLE B-LAYER**

923 In Run 2, a new innermost pixel layer, known as the insertable B-layer (IBL), was added to the Inner
924 Detector [53]. This layer was added to cope with the higher luminosities planned in LHC Run 2 and at the
925 high luminosity HL-LHC. Additionally it improves tracking position resolution which in turn improves
926 the vertexing and *b*-tagging capabilities in ATLAS. The detector sits directly on a new beam pipe, only
927 33.25 mm away from the collision points in the azimuthal plane.

928 **SEMICONDUCTOR TRACKER (SCT)**

929 The semiconductor tracker (SCT) consists of silicon microstrips and comprises the next four layers of
930 the ID. This sub-detector has 6.4 cm long sensors that are daisy-chained into strips with a strip pitch of
931 80 μm [44]. Some of the strips have a small stereo angle to allow for measurement of both angular co-
932 ordinates. In total there are 6.3 million readout channels. The intrinsic accuracies are 17 μm in $R\text{-}\phi$ and
933 580 μm in z (or R in the endcap).

934 **TRANSITION RADIATION TRACKER (TRT)**

935 The transition radiation tracker (TRT) serves two purposes. First, it consists of 4 mm diameter straw tubes
936 filled with a 70/27/3% gas mixture of xenon, carbon dioxide, and oxygen to provide tracking of charged
937 particles. Particles typically have 36 TRT straw tube hits per track. The material in between the straws
938 is designed to induce transition radiation which can be useful for particle identification. As particles pass
939 between media with different dielectric constants, they emit transition radiation that can cause additional
940 showers in the TRT. In particular it is useful for discrimination between electrons and pions or other
941 charged hadrons, as the amount of transition radiation is proportional to the Lorentz factor of the particle.

942 **2.2.3 CALORIMETERS**

943 The calorimeter system consists of two main sub-components: a fine granularity electromagnetic calorime-
944 ter tailored for the measurement of photons and electrons and multiple coarser hadronic calorimeters ded-
945 icated to the measurement of hadronic showers [44]. The calorimeter system has broader coverage than

946 the inner detector, covering the region out to $|\eta| < 4.9$. It is also designed to deliver good containment of
947 showers so as to limit leakage into the muon system. Figure 2.5 shows the layout of the calorimeter system.

948 Both the electromagnetic and hadronic calorimeters are sampling calorimeters. They alternate active
949 material for energy measurement with passive material for energy absorption. The materials used for each
950 purpose vary based on the type of calorimeter and its location in the detector.

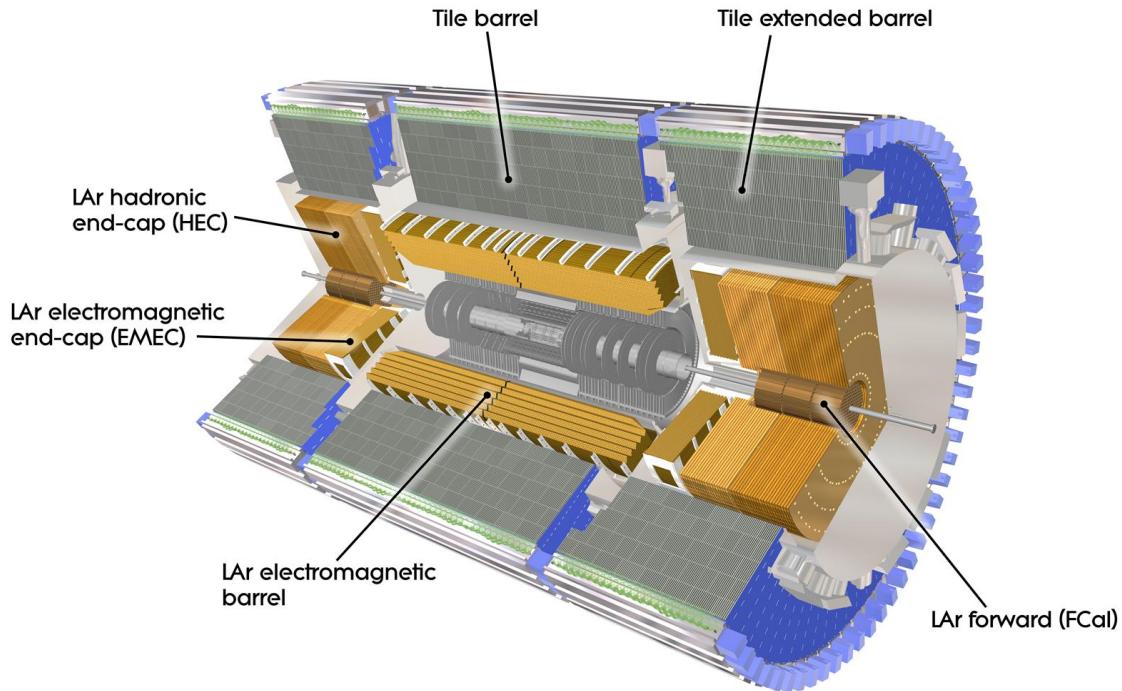

Figure 2.5: Layout of the ATLAS calorimeter system [44].

951 ELECTROMAGNETIC CALORIMETER

952 The electromagnetic calorimeter (EM calorimeter) use liquid Argon (LAr) as its active material and lead
953 as its passive material. It is arranged in an accordion geometry to increase the absorption area while still
954 allowing it to have no azimuthal cracks (complete symmetry in ϕ). The EM calorimeter is divided into a
955 barrel portion that extends to $|\eta| < 1.475$ and an endcap portion going from $1.375 < |\eta| < 3.2$. The
956 region where these two units overlap is called the “transition region”.

957 In order to provide good containment the calorimeter depth must be optimized. Typically, for elec-
958 tromagnetic calorimeters the depth is measured in radiation lengths. In general, the intensity of a particle
959 beam attenuates exponentially in distance with an attenuation constant equal to the radiation length. That
960 is, $I(x) = I_0 e^{-x/X_0}$, where I is the intensity, x is the distance traveled, and X_0 is the radiation length.
961 The ATLAS EM calorimeter is designed to have > 22 radiation lengths in the barrel and > 24 in the
962 endcap [44].

963 **HADRONIC CALORIMETERS**

964 There are three types of hadronic calorimeters present in ATLAS: the tile calorimeter (TileCal), hadronic
965 endcap (HEC), and forward calorimeter (FCal). Each one is optimized for stopping of hadronic showers
966 and the materials chosen are specific to their placement in the detector.

967 The TileCal is a scintillating tile calorimeter placed directly outside the EM calorimeter. It uses steel as
968 the absorber and plastic scintillator tiles as the active material. It has coverage in the barrel at $|\eta| < 1.0$
969 and in the “extended barrel” region of $0.8 < |\eta| < 1.7$.

970 The HEC had two wheels perpendicular to the beam line per endcap and is located directly behind the
971 EM calorimeter endcap modules. The HEC covers the region from $1.5 < |\eta| < 3.2$, overlapping slightly
972 with both the tile calorimeter and the forward calorimeter. Like the EM calorimeter, it uses liquid Argon
973 as the active material, but it uses copper as the absorber.

974 The FCal covers the most forward regions of the calorimeter system, extending to the region of $3.1 <$
975 $|\eta| < 4.9$. It again uses liquid argon as its active material. For absorber, it consists of an innermost module
976 made of copper followed by a module made of tungsten.

977 The hadronic equivalent of radiation length is called the interaction length and is denoted as λ . In the
978 barrel, the hadronic calorimeter depth is approximately 9.7λ , while in the endcap is is 10λ . The outer
979 supports contribute an additional 1.3λ . This is been shown to be sufficient to limit punch-through of
980 showers to the muon system [44].

981 2.2.4 MUON SPECTROMETER

982 The muon spectrometer is dedicated to measuring the momentum and position of muons. It consists
983 of tracking and trigger chambers which are unique in the barrel and endcap regions. The magnetic field
984 for bending of muons is provided by a system of three large air-core toroid magnets (from which ATLAS
985 derives its name.) These magnets provide 1.5 to 5.5 Tm of bending power at $0 < |\eta| < 1.4$ and approx-
986 imately 1 to 7.5 Tm in the endcap region of $1.6 < |\eta| < 2.7$. The entire muon system covers the range
987 $0 < |\eta| < 2.7$. Monitored drift tubes (MDTs) are used for tracking in the barrel and the two outer layers
988 of the endcap, while cathode strip chambers (CSCs) are used to provide tracking in the innermost endcap
989 wheel. In the barrel, resistive plate chambers (RPCs) are used as trigger chambers while thin gap chambers
990 (TGCs) are used in the endcap. Figure 2.6 shows the layout of the ATLAS muon system. The entire muon
991 system is designed with the specification of providing a 10% momentum resolution for a 1 TeV muon.

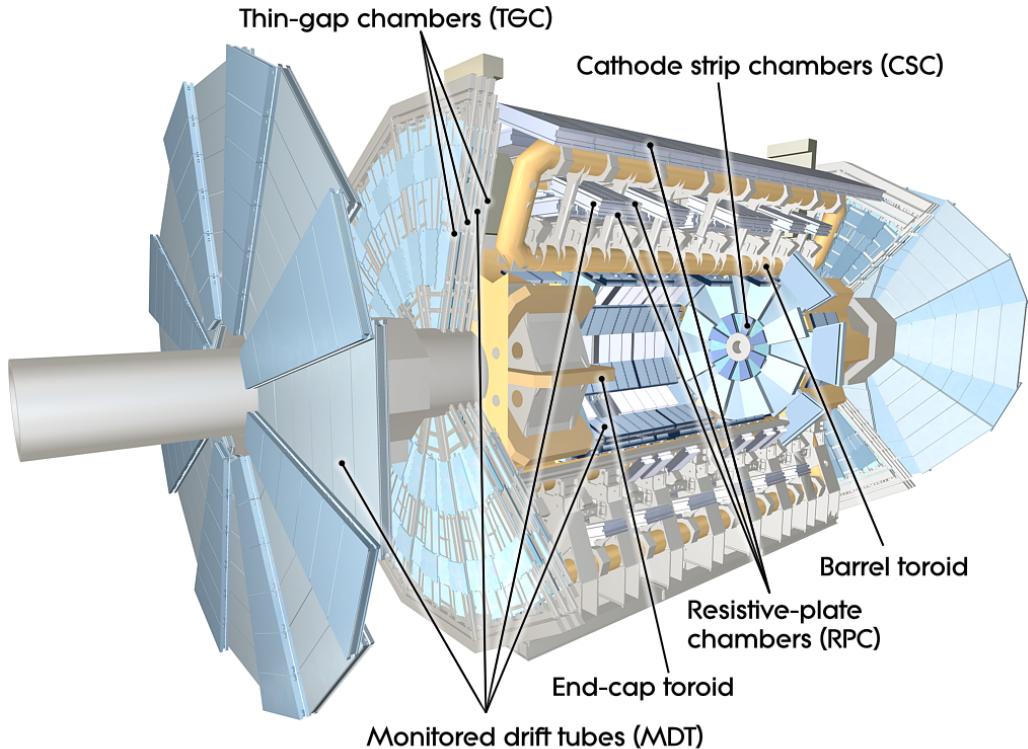

Figure 2.6: Layout of the ATLAS muon system [44].

992 MONITORED DRIFT TUBES (MDTs)

993 The monitored drift tubes (MDTs) are aluminum 3 cm diameter tubes filled with a 93/7 % mixture of
994 Argon and CO₂, with trace amounts of water. As a charged particle traverses the tube, it ionizes the gas
995 and the ions drift to a wire at the center of the tube. The radial distance of traversal of the particle in the
996 tube is determined by the drift time of the electrons, allowing for fine position resolution. The tubes have
997 an average resolution of 80 μm per tube and a maximum drift time of approximately 700 ns. The tubes
998 are oriented so that they give precision measurement in η and run along ϕ . They cover $|\eta| < 2.7$, except
999 in the innermost layer of the endcap where they only go to $|\eta| < 2.0$ [44].

1000 CATHODE STRIP CHAMBERS (CSCs)

1001 The cathode strip chambers cover a narrow window of the innermost endcap region at $2.0 < |\eta| <$
1002 2.7. In this region the background rates in the cavern are particularly high and the CSCs are designed to
1003 handle these higher rates. The CSCs are multiwire proportional chambers with wires pointing in the radial
1004 direction (away from the beam pipe). The wire serves as an anode and there are two types of segmented
1005 cathode strip, one perpendicular to the wires which gives the precision measurement and one parallel which
1006 provides the transverse coordinate. It has an 80/20% gas mixture of Argon and CO₂ [44].

1007 RESISTIVE PLATE CHAMBERS (RPCs)

1008 The resistive plate chambers (RPCs) are gaseous electrode-plate detectors covering the region $|\eta| < 1.05$.
1009 They consist of two resistive plates separated by a distance of 2 mm. The gas mixture used is a 94.7/5/0.3%
1010 mixture of C₂H₂F₄, Iso-C₄H₁₀, and SF₆. It has readout strips with a pitch of 23-35 mm for both η and
1011 ϕ measurement and thus provides measurement of the azimuthal coordinate in the barrel. The thin gas
1012 gap allows for a quick response time which makes it ideal for use in the trigger. Signals in the RPC have
1013 a width of approximately 5 ns. There are three layers of RPCs which are referred to as the three trigger
1014 stations. They allow for programmable thresholds in both a low p_T and high p_T trigger. The coincidence
1015 of hits in the innermost chambers allows for setting muon trigger thresholds between 6 and 9 GeV, while
1016 the outermost layer allows the trigger to set trigger thresholds in the range of 9 to 40 GeV [44].

1017 THIN GAP CHAMBERS (TGCs)

1018 The thin gap chambers (TGCs) are multiwire proportional chambers where the wire to cathode distance
1019 (1.4mm) is smaller than the wire-to-wire distance (1.8 mm). They contain a gas mixture of CO₂ and *n*-
1020 pentane and use a high electric field to gain good time resolution. They serve two functions in the end-cap
1021 system. First, they serve as the trigger chambers. Second, they also provide azimuthal coordinate measure-
1022 ment. They sit on the inner and middle layers of the endcap. The outermost layer's azimuthal coordinate
1023 is determined by extrapolation [44]. As with the RPCs, the TGCs also are capable of triggering with pro-
1024 grammable thresholds in the same p_T range specified for the RPCs above.

1025 2.2.5 MAGNET SYSTEM

1026 As mentioned previously, there are two independent magnet systems in ATLAS. The first is a 2 T solenoid
1027 field in the inner detector which provides bending in the azimuthal plane. The second is an approximately
1028 0.5 T toroidal field in the muon system which provides bending in η . Figure 2.7 shows the predicted field
1029 integral as a function of $|\eta|$ [44].

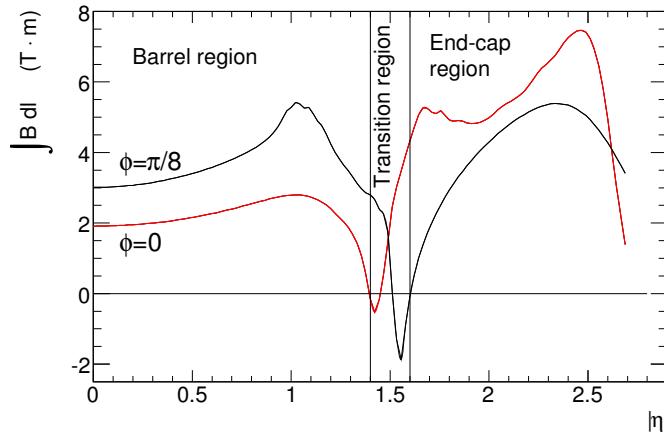

Figure 2.7: Predicted field integral as a function of $|\eta|$ for the ATLAS magnet system [44].

1030 2.2.6 TRIGGER SYSTEM

1031 The ATLAS trigger system searches for signatures of muons, electrons, photons, hadronically decaying τ
 1032 leptons, and jets in order to save these events for further analysis. The trigger system in ATLAS is designed
 1033 to reduce the maximum LHC event rate of 40 MHz to a more reasonable rate that can be recorded. The
 1034 trigger first consists of a fast, hardware based system called the Level-1 (L1) trigger. The L1 trigger consists
 1035 of independent dedicated detector sub-components that can seed regions of interest (RoIs) for further
 1036 analysis downstream. For muons, the RPCs and TGCs are used, while in the calorimeter coarsely grained
 1037 sections of calorimeter cells called towers are used. Once regions of interest are seeded, a software based
 1038 system called the High Level Trigger (HLT) is used to reconstruct objects and integrate information from
 1039 different parts of the detector. In Run 1 of ATLAS, the HLT consisted of two separate stages: the level 2
 1040 (L2) trigger and the event filter (EF).

1041 The maximum trigger rate that the L1 trigger can handle is 75 kHz. In the HLT, the rate of events
 1042 written to disk is approximately 400 Hz. Figure 2.8 shows the trigger rates for different L1 triggers in 2012
 1043 and 2015 for ATLAS [54].

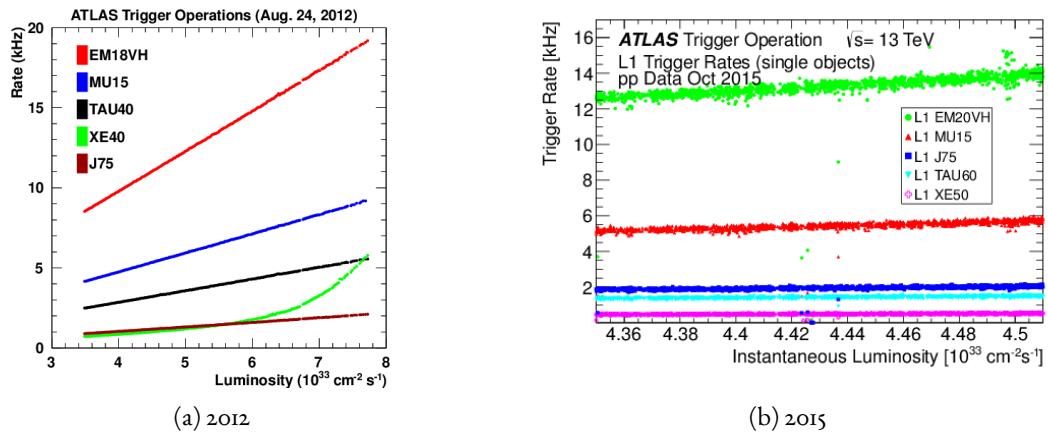

Figure 2.8: ATLAS trigger rates for Level-1 triggers as a function of instantaneous luminosity in 2012 and 2015 operation. These are single object triggers for electromagnetic clusters (EM), muons (MU), jets (J), missing energy (XE), and τ leptons (TAU). The threshold of the trigger is given in the name in GeV [54].

1044 2.2.7 ATLAS DATASETS

1045 ATLAS has collected data at center of mass energies of 7, 8, and 13 TeV. Figure 2.9 shows the integrated
1046 luminosity as a function of time for each of the three datasets. In the 2011 dataset with $\sqrt{s} = 7$ TeV,
1047 ATLAS recorded 5.08 fb^{-1} . Increased instantaneous luminosity in 2012 led to a larger dataset of 21.3 fb^{-1}
1048 recorded at $\sqrt{s} = 8$ TeV. After Long Shutdown 1 (LS1) of the LHC and a restart in 2015, ATLAS
1049 recorded 3.9 fb^{-1} of data at $\sqrt{s} = 13$ TeV [55, 56]. The data recorded by ATLAS can only be used for
1050 analysis if the required sub-detectors were in a stable state when the data was being taken. The fraction
1051 of recorded ATLAS data that was labeled as being good for physics analysis was 90%, 95%, and 82% in
1052 the 7, 8, and 13 TeV data respectively. Thus, the Run 1 results presented in this thesis use 4.6 fb^{-1} at
1053 $\sqrt{s} = 7$ TeV and 20.3 fb^{-1} at $\sqrt{s} = 8$ TeV¹. The Run 2 results use 3.2 fb^{-1} at $\sqrt{s} = 13$ TeV.

1054 2.2.8 DETECTOR PERFORMANCE

1055 Table 2.2 summarizes the design requirements for each of the different sub-detectors. This table shows the
1056 energy and momentum resolution of tracking, calorimetry, and muon measurements.

	Required resolution
Tracking	$\sigma_{p_T}/p_T = 0.05\% p_T \oplus 1\%$
EM calorimetry	$\sigma_E/E = 10\%/\sqrt{E} \oplus 0.7\%$
Hadronic calorimetry	
Barrel and end-cap	$\sigma_E/E = 50\%/\sqrt{E} \oplus 3\%$
Forward	$\sigma_E/E = 100\%/\sqrt{E} \oplus 10\%$
Muon spectrometer	σ_{p_T}/p_T at $p_T = 1$ TeV

Table 2.2: Performance requirements for the ATLAS detector [44].

1057 2.3 THE ATLAS MUON NEW SMALL WHEEL UPGRADE

1058 As the LHC continues operation, it is scheduled to be upgraded in several phases to allow it to reach higher
1059 instantaneous luminosities and thus collect larger datasets. These conditions will open new doors for study

¹The analyses combined in the Higgs discovery (presented in chapter 4) use between 4.6 and 4.8 fb^{-1} at 7 TeV depending on which detectors are required to be in a stable state. The discovery also only uses the 5.8 fb^{-1} of 8 TeV data that was available at the time of the analysis.

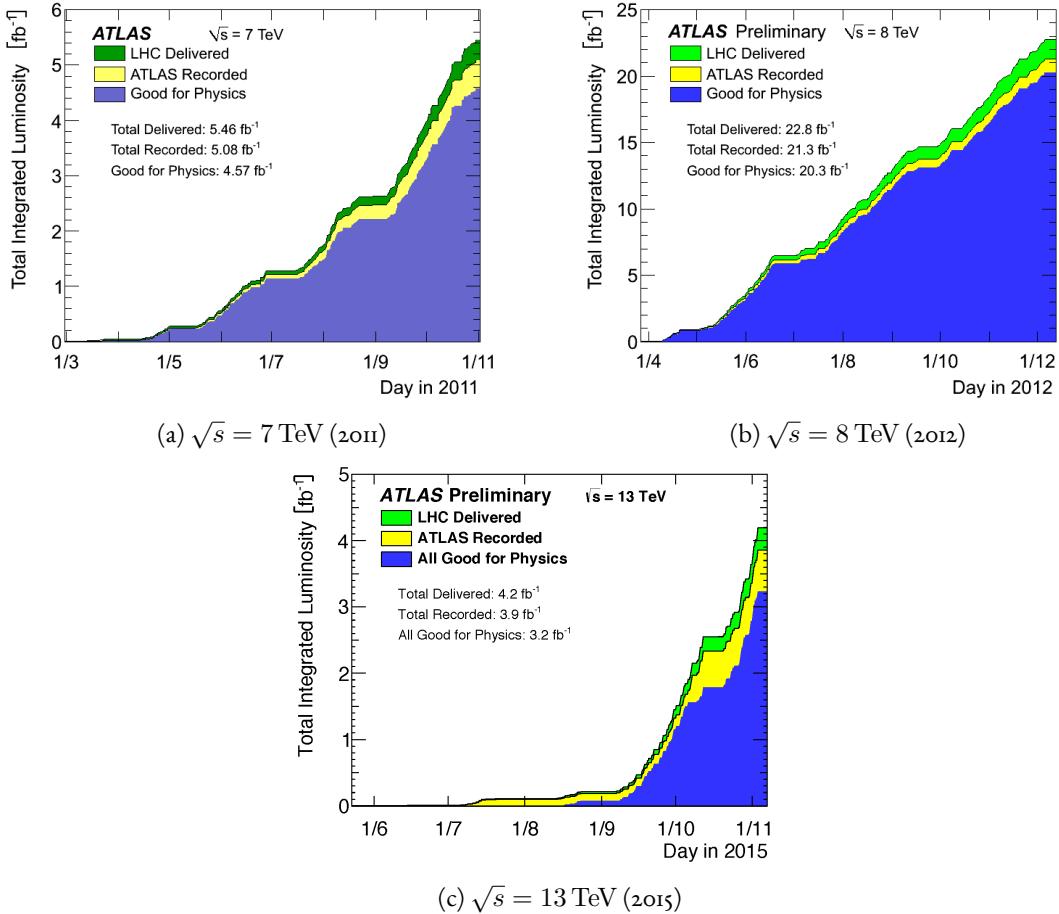

Figure 2.9: Instantaneous luminosity as a function of time for data recorded by ATLAS at different center of mass energies [55, 56].

of rare physics processes but will also present interesting challenges that must be faced. ATLAS will require new detector technologies to cope with the increased background rates in the cavern in these high luminosity conditions. One such upgrade, scheduled to be installed during Long Shutdown 2 (LS2) of the LHC in 2018, is the ATLAS Muon New Small Wheel (NSW) [57]. The NSW will replace the innermost end-cap wheel of the muon system with new technologies. This is the part of the muon detector closest to the beam line and thus experiences the highest rates of particle flux in the muon system.

1066 2.3.1 MOTIVATION

1067 The motivation of the NSW is two-fold. The first objective is to alleviate the decreased tracking efficiency
1068 that comes in a high rate environment. As shown in figure 2.10, at the LHC design luminosity both the
1069 efficiency of recording hits and reconstructing track segments in the MDTs decreases. While the MDTs
1070 were designed to cope with the hit rates at the LHC design luminosity, the High Luminosity LHC will
1071 exceed these design specifications and the MDTs will have to be replaced.

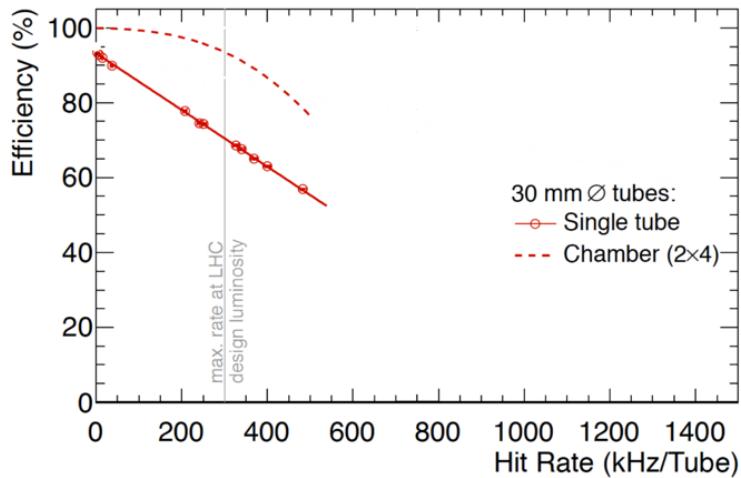

Figure 2.10: MDT tube hit (solid) and segment (dashed) efficiency as a function of hit rate per tube [57].

1072 The NSW will also work to alleviate the rate of fake triggers arising in the endcap. Figure 2.11 shows the
1073 extrapolated trigger rates as a function of the p_T threshold with and without the NSW upgrade. As the
1074 figure shows, the NSW upgrade will reduce the trigger rate considerably compared to the current endcap
1075 trigger system. At a p_T threshold of 20 GeV, the level-1 trigger rate drops from 20 kHz to 7 kHz. This
1076 reduction allows the p_T thresholds on muons to remain low, increasing the phase space of possible physics
1077 studies and in particular maintaining good acceptance for Higgs physics.

1078 2.3.2 NSW DETECTOR TECHNOLOGIES

1079 The NSW will use two new detector technologies - micromesh gaseous structure detectors (micromegas)
1080 and small-strip thin gap chambers (sTGCs) [57, 58]. The micromegas is more suited to tracking because

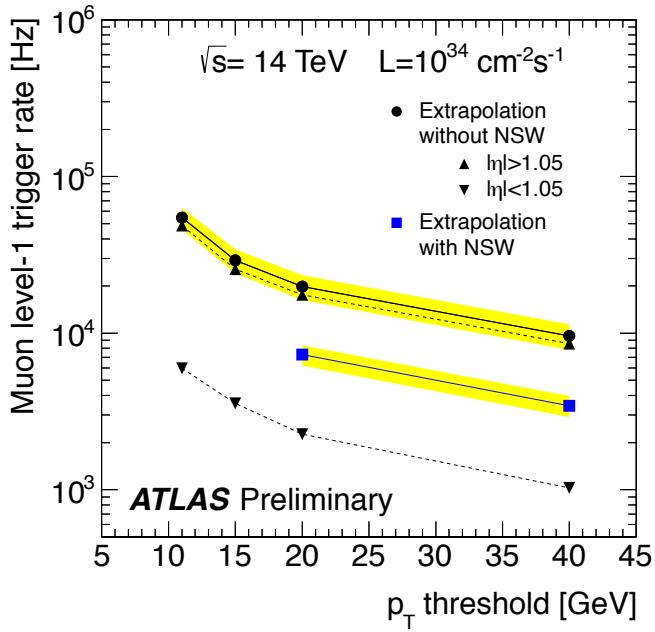

Figure 2.11: Trigger rate as a function of p_T threshold with and without the NSW upgrade [57].

of its good spatial resolution, while the sTGCs have better time resolution and are more suited for the trigger. However, both systems are capable of providing tracking and trigger information. To maintain full redundancy in cases of detector failure, both technologies will be used for tracking and trigger in the NSW.

1085 MICROMEGAS

1086 Micromegas detectors operate using a thin metallic mesh that sits approximately $100\ \mu\text{m}$ away from the
 1087 readout electrodes to create the amplification region. Above this mesh, there is a drift region on the order
 1088 of a few mm in length capped by a drift electrode. As a charged particle traverses the detector, it ionizes gas
 1089 and the electrons drift down towards readout strips. The timing of the drift can be used to reconstruct the
 1090 angle of traversal of the particle. This is illustrated in figure 2.12. The micromegas used in ATLAS will be
 1091 resistive micromegas, where the readout electrodes are topped with resistive strips [59]. This alleviates the
 1092 risk of sparking in the large area detectors that ATLAS will use.

1093 In ATLAS, the micromegas drift gap will be 5 mm and the amplification gap will be $128\ \mu\text{m}$. They are

1094 filled with the same gas mixture as the MDTs. They will be stacked in an octuplet in an XXUV-UVXX
 1095 geometry, where X refers to nominal strips and U and V refer to stereo strips at an angle of $\pm 1.5^\circ$. This
 1096 arrangement allows for measurement of the azimuthal coordinate and gives a large lever arm between the
 1097 straight strips for triggering purposes. Figure 2.12 shows the geometry of a single micromegas detector as
 1098 well as its operating principle [57].

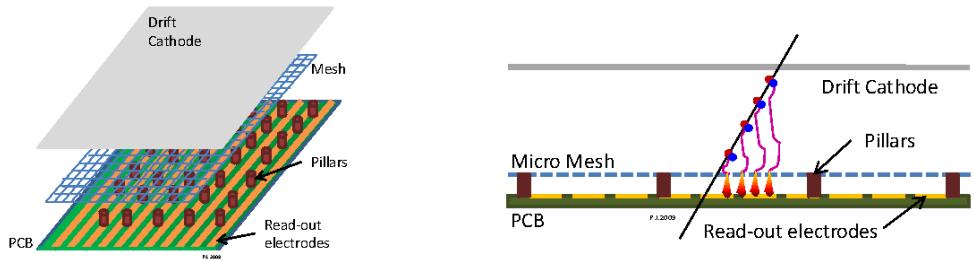

Figure 2.12: Illustrations of the geometry (left) and operating principle (right) of the micromegas detector [57].

1099 sTGCs

1100 The sTGCs are similar to the TGCs currently in the ATLAS endcap muon system [44]. They consist
 1101 of gold-plated tungsten wires (with a 1.8 mm pitch) between two cathode planes 1.4 mm away from the
 1102 wire plane. One cathode plane consists of strips with a 3.2 mm pitch (much smaller pitch than the TGCs),
 1103 while the other consists of coarser pads that are used for defining regions of interest in the sTGC trigger
 1104 algorithm. Figure 2.13 shows the basic detector geometry.

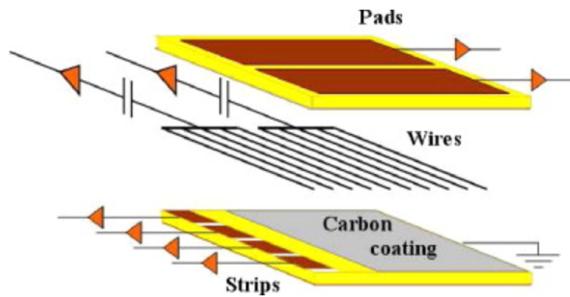

Figure 2.13: Geometry of the sTGC detector [57].

1105 2.3.3 PHYSICS IMPACT

1106 Maintaining low p_T thresholds for muons while still staying within the trigger rate budget at Level 1 for the
1107 muon system (20 kHz) is crucial for physics analyses to be successful in high luminosity conditions. One
1108 realm where the lepton trigger threshold is especially important is in Higgs physics. In the $H \rightarrow WW^*$
1109 analysis, one of the W bosons is off shell and tends to decay to soft leptons. In associated production of a
1110 Higgs with a W , the lepton is also important because it provides the main handle which allows the event
1111 to be triggered. Without the NSW, analyses would be required to either raise the muon p_T threshold or
1112 only use muons triggered from the barrel muon system. Table 2.3 shows that both of these alternatives
1113 significantly reduce the Higgs signal efficiency. With the NSW, the signal efficiency is largely maintained
1114 and the triggers can remain unprescaled at lower p_T thresholds.

Threshold	$H \rightarrow b\bar{b}$ (%)	$H \rightarrow WW^*$ (%)
$p_T > 20$ GeV	93	94
$p_T > 40$ GeV	61	75
$p_T > 20$ GeV (barrel only)	43	72
$p_T > 20$ GeV (with NSW)	90	92

Table 2.3: Signal efficiencies for WH production with $H \rightarrow b\bar{b}$ and $H \rightarrow WW^* \rightarrow \mu\nu qq$ under different trigger configurations [57].

1115 2.4 OBJECT RECONSTRUCTION IN ATLAS

1116 ATLAS analyses first start by requiring the presence of certain reconstructed physics objects in the event.
1117 This section will present a brief overview of the algorithms used to reconstruct electrons, muons, jets (in-
1118 cluding b -jets), and missing energy². The performance of physics object reconstruction and identification
1119 will also be discussed as these are relevant to the analyses presented later. Figure 2.14 gives an overview of
1120 the different sub-detectors that each type of particle will interact with in ATLAS.

²Reconstruction algorithms for other objects, such as photons and hadronically decaying τ leptons, are not detailed here as these objects are not used in the results presented in this dissertation.

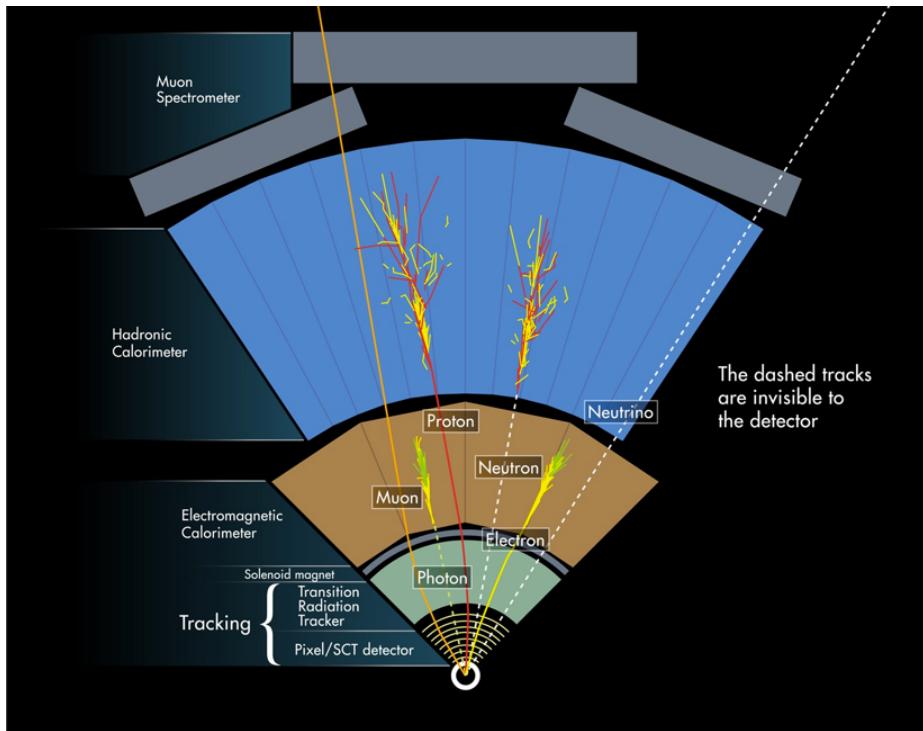

Figure 2.14: Illustration of particle interactions in ATLAS [60]

1121 2.4.I ELECTRONS

1122 Electrons in ATLAS will leave tracks in the inner detector and energy deposits in the electromagnetic
1123 calorimeter. The algorithm for recognizing the signature of electrons proceeds in two steps: reconstruction
1124 and identification.

1125 In reconstruction, an electron candidate is formed by matching EM calorimeter deposits with ID tracks.
1126 The algorithm first chooses seed clusters in the EM calorimeter by using a sliding window algorithm that
1127 searches for towers with transverse energy larger than 2.5 GeV. In addition to seed clusters, track candi-
1128 dates must be identified in the ID. The algorithm selects seed tracks with $p_T > 1$ GeV that do not fit well
1129 with a pion hypothesis. Once candidate tracks are selected, they are re-fit with a Gaussian Sum Filter (GSF)
1130 algorithm to estimate electron parameters [61]. Finally, an electron candidate is formed if at least one track
1131 matches to a seed cluster in the calorimeter. The full details of the reconstruction algorithm can be found
1132 in reference [62].

1133 Once an electron candidate is present, identification criteria must be applied in order to reject fake elec-

trons from background. Many different variables are used for this identification. They include information about the shower shape in the EM calorimeter and the amount of leakage into the hadronic calorimeter, as well as information from the ID and in particular the TRT. There are both selection requirement based and likelihood-based criteria that range from “loose” to “very tight”. For details, see reference [62].
 In the $H \rightarrow WW^*$ analysis, both medium and very tight likelihood electrons are used depending on the electron p_T .

Figure 2.15 shows the algorithm’s reconstruction efficiency for true electrons with different identification criteria as well as the electron energy resolution in simulation [62, 63]. The reconstruction efficiency is measured using both the Z and J/ψ with 8 TeV data.

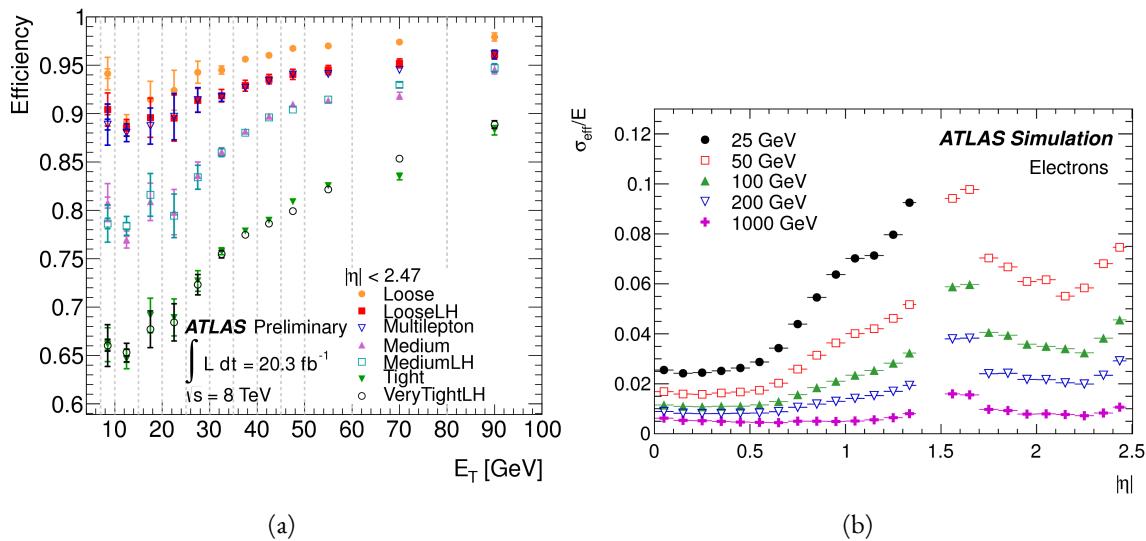

Figure 2.15: Electron performance: (a) reconstruction efficiency as a function of electron E_T [62] (b) energy resolution in simulation as a function of $|\eta|$ for different energy electrons [63].

2.4.2 MUONS

The ATLAS detector is designed to stop most particles before they reach the muon spectrometer. Muons, however, are minimum ionizing particles, meaning that they will not lose a significant amount of energy through interactions with the detector and will thus pass through. Therefore, the muon reconstruction works to match tracks in the muon spectrometer with tracks in the inner detector.

1148 The first step of reconstruction is to reconstruct local straight line tracks, called segments, in each muon
1149 chamber. Segments are then fit to larger tracks that traverse the entire muon spectrometer. Such muon
1150 tracks are referred to as “standalone” tracks (SA) as they only use information from the muon spectrometer.
1151 The standalone tracks are then matched to tracks in the inner detector to form “combined” (CB) muons,
1152 and both tracks are used to determine the momentum and direction of the muon. To improve acceptance,
1153 segment-tagged and calorimeter-tagged muons are also reconstructed. In these cases, ID tracks are matched
1154 to segments in the MS and calorimeter deposits consistent with a minimum ionizing particle, respectively.
1155 The details of the reconstruction can be found in reference [64].

1156 As with electrons, once muon candidates are reconstructed they have identification criteria applied to
1157 reduce background. These criteria include the χ^2 match between the ID and MS tracks, the number of
1158 hits in the ID, overall ID and MS track fit quality, and additional variables. In Run 1, the muons used are
1159 simply referred to as combined muons [64]. In Run 2, an improved reconstruction algorithm is used and
1160 criteria ranging from “loose” to “tight” are defined (similar to what is done with electrons) [65]. Figure 2.16
1161 shows the muon reconstruction efficiency (measured with the Z and J/ψ) and invariant mass resolution
1162 in $\sqrt{s} = 8$ TeV data.

1163 2.4.3 JETS

1164 When a quark or gluon is produced in collisions, it is not measured directly in ATLAS. Rather, due to
1165 QCD effects, it produces a collimated spray of hadrons in the direction of the original parton, which is
1166 known as a jet. Jets are reconstructed in ATLAS using energy deposits in the hadronic calorimeter. The
1167 first step is build “topological clusters” out of energy deposits in calorimeter cells [66, 67]. This is done
1168 using strategy where seed cells are chosen by picking cells whose energy measurements are four times the
1169 amount of noise expected for that cell. Adjacent cells with at least 2σ energy measurements are added to
1170 the cluster, then a final layer of clusters with energy above 0σ are added. Once calorimeter clusters are
1171 formed, they are clustered further into jet candidates. The analyses presented in this thesis use the anti- k_T
1172 jet clustering algorithm [68]. This algorithm defines a parameter R that appears in the denominator of
1173 the clustering distance metric and defines the radial size of the jet in η - ϕ space.

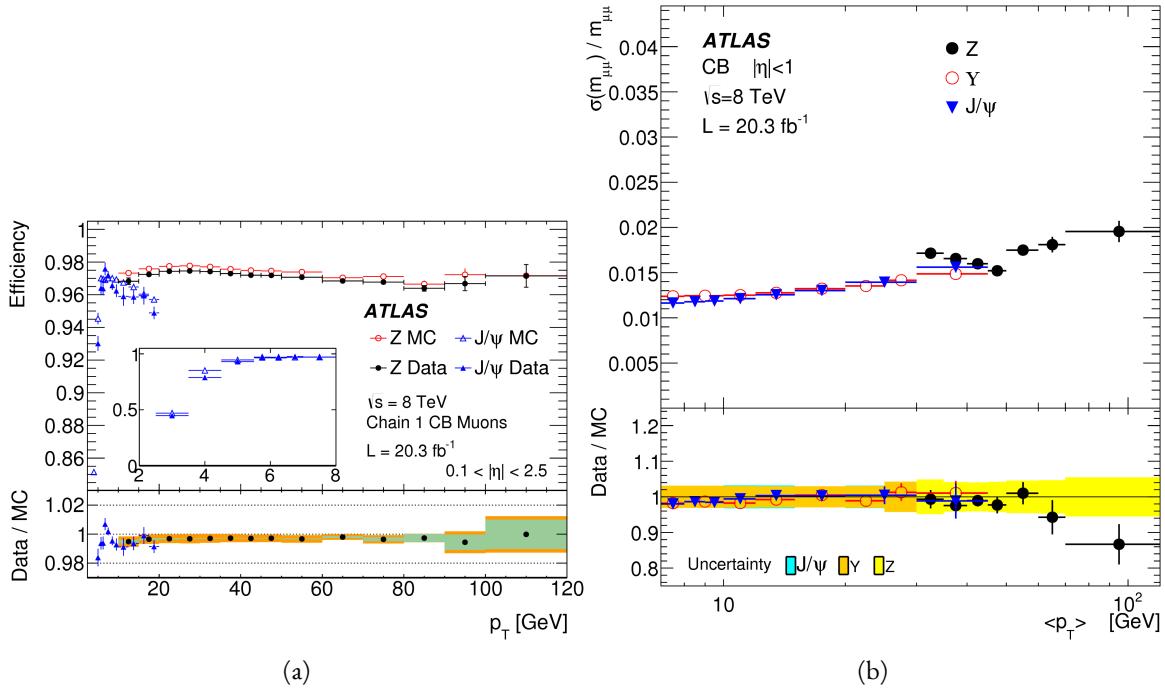

Figure 2.16: Muon performance in $\sqrt{s} = 8$ TeV data: (a) reconstruction efficiency as a function of muon p_T (b) dimuon mass resolution as a function of average p_T [64].

1174 The energy response of the calorimeter must be properly characterized in order to reconstruct the true
 1175 jet energy. Calorimeter clusters can be calibrated either with the EM calibration, where each cluster is as-
 1176 sumed to have come from the energy deposit of an electron or photon, or the LCW calibration, where local
 1177 cluster weights are computed to allow for local calibration of clusters as hadronic or electromagnetic. The
 1178 details of the jet energy calibration are not discussed here and are presented in reference [69]. Figure 2.17
 1179 shows the jet energy response after calibration in Monte Carlo as a function of the true p_T of the jet [69].

1180 Analyses often need to know how consistent a particular jet is with the primary vertex of the event in
 1181 order to avoid contamination from pileup interactions. One measure of this consistency is known as the
 1182 jet vertex fraction (JVF). The JVF is the ratio of tracks associated with a primary vertex to the total number
 1183 of tracks inside a jet. Jets from the primary interaction in the event should have a large fraction of tracks
 1184 consistent with the primary vertex and therefore have a large JVF value.

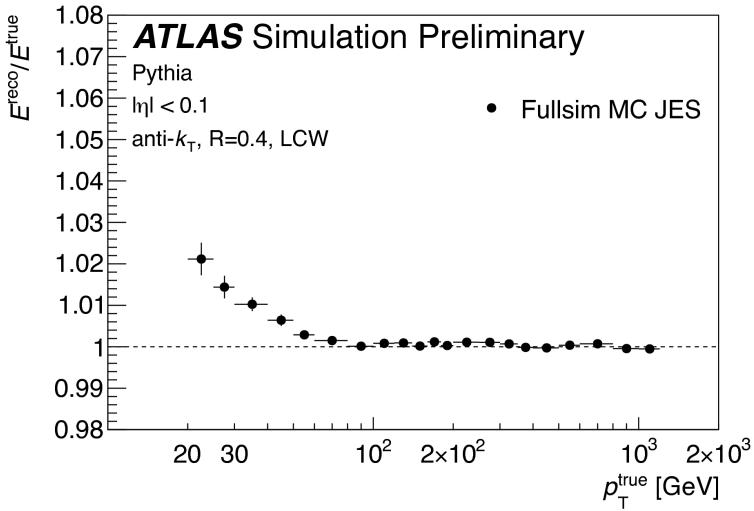

Figure 2.17: Jet energy response after calibration as a function of true p_T in simulation [69].

1185 2.4.4 b -TAGGING

1186 One important aspect of jet physics is the task of identifying the flavor of parton that produced the mea-
 1187 sured jet. While in general this is very difficult, jets from b -quarks offer an interesting case where such
 1188 identification is possible. B mesons have a lifetime on the order of 10^{-12} seconds, which makes a $c\tau$ of
 1189 0.5 mm [6]. This type of displaced decay vertex can be identified in detectors like ATLAS and allows b -jets
 1190 to be distinguished from other flavors of jets³. With boosts, B mesons can travel for several millimeters
 1191 before decaying.

1192 ATLAS uses several algorithms, including a multivariate machine learning technique, to identify jets
 1193 from b -quarks. The inputs to the multivariate algorithm are determined from lower level reconstruction
 1194 algorithms. There are three distinct algorithms that reconstruct variables which are used as input to the
 1195 multivariate technique.

1196 The first family of algorithms is referred to as IPx D (where the x can either be 2 or 3). These algorithms
 1197 use the transverse and longitudinal impact parameters d_0 and z_0 of the tracks inside a jet to determine their
 1198 consistency with the primary vertex. They use two or three dimensional (hence the x) templates for light

³Jets from charm quarks can also be detected in this way but they do not live quite as long so the displacement of the vertex is harder to distinguish

1199 flavor, charm, and bottom jets and then evaluate the likelihood of the jet coming from each of these types.

1200 The likelihood ratios are used as inputs to the multivariate algorithm.

1201 The next two algorithms used as input are referred to as the secondary vertex (SV) and JetFitter (JF)
1202 algorithms. The SV algorithm uses tracks inside the jet to fit for vertices that are displaced from the pri-
1203 mary vertex. The JF algorithm attempts to reconstruct the full flight path of the b by looking for multiple
1204 displaced vertices along the same line (as B decays often result in subsequent charm meson decays).

1205 In Run 1, the multivariate b -tagging algorithm used a neural network and was referred to as MV1. The
1206 details of this algorithm and its inputs are given in reference [70]. This algorithm is used for defining
1207 a veto on b -jets in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis presented in Part 2. In Run 2, the number of
1208 inputs was simplified and a boosted decision tree with 24 input variables was used, referred to as MV2 [71].
1209 The MV2 algorithm is a boosted decision tree incorporating twenty-four input variables constructed from
1210 three lower level input algorithms described above. This algorithm is used for b -tagging in the $X \rightarrow$
1211 $HH \rightarrow b\bar{b}b\bar{b}$ search presented in Part 3. Figure 2.18 summarizes the inputs to MV2. Figure 2.19 shows the
1212 performance of each of these algorithms in Run 1 and Run 2.

IP2D and IP3D (6 inputs)	SV1 (8 inputs)	JetFitter (8 inputs)
$\log(p_b/p_u)$	Mass	Mass
$\log(p_b/p_c)$	Energy fraction	Energy fraction
$\log(p_c/p_u)$	# tracks at vertex	# vertices
	# 2 track vertices	# tracks at vertex
	Lxy	# 1 track vertices
	L3d	# 2 track vertices
	3D significance	3D significance
	ΔR	ΔR
Kinematics (2 inputs)		
	p_T	
	η	

Figure 2.18: Summary of the inputs to the MV2 b -tagging algorithm.

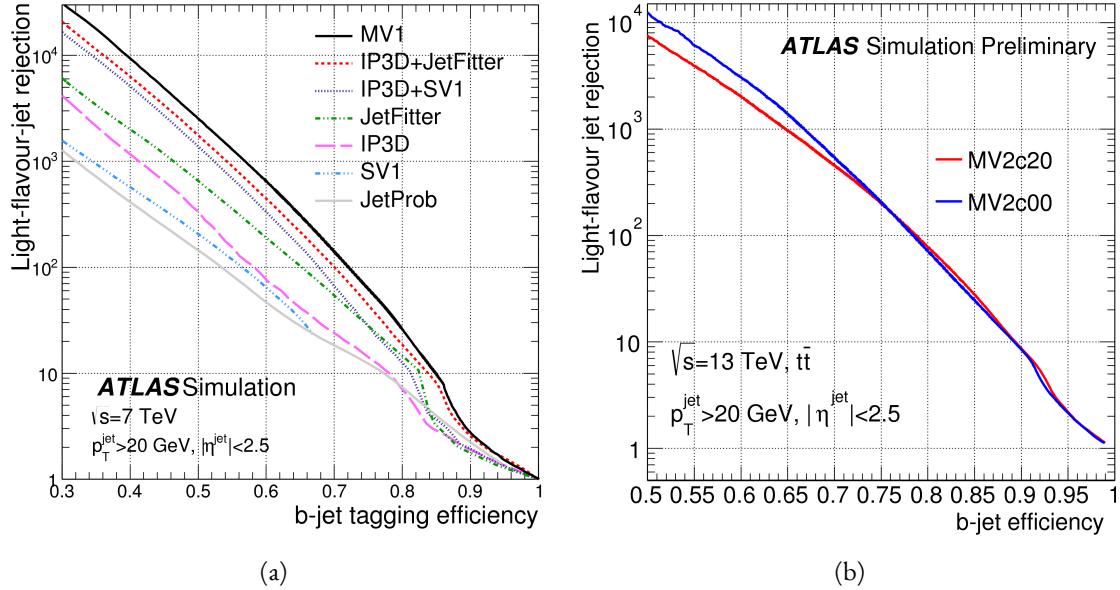

Figure 2.19: Light jet rejection ($1/\text{efficiency}$) vs. b -jet efficiency for MV1 and its input algorithms (a) [70] and MV2 (b) [71] in simulated $t\bar{t}$ events. The numbers in the algorithm names in (b) refer to the fraction of charm events used in the MV2 training.

1213 2.4.5 MISSING TRANSVERSE ENERGY

1214 As noted in figure 2.14, neutrinos produced in ATLAS will pass through the detector without interacting.
 1215 The only way of detecting the presence of weakly interacting particles like neutrinos (or BSM particles
 1216 that are long-lived) is to use missing transverse momentum. The basic principle of missing transverse en-
 1217 ergy is to use the momentum balance of the incoming protons to infer the presence of missing particles.
 1218 The net longitudinal momentum of the incoming partons that collide is not known (since each carries
 1219 an unknown fraction of the proton's momentum). However, the protons (and thus incoming partons)
 1220 have essentially no net momentum in the plane transverse to the beam line (the x - y plane). Therefore, if
 1221 there are no undetected particles in the final state, the transverse momenta of all of the final state particles
 1222 should balance. The magnitude of the imbalance in the transverse plane is known as missing transverse
 1223 momentum (E_T^{miss}).

1224 The basic calculation of missing transverse momentum from calorimeter cells is given in equation 2.4 [72].

1225

$$\begin{aligned} E_x^{\text{miss}} &= -\sum_{i=1}^{N_{\text{cell}}} E_i \sin \theta_i \cos \phi_i \\ E_y^{\text{miss}} &= -\sum_{i=1}^{N_{\text{cell}}} E_i \sin \theta_i \sin \phi_i \end{aligned} \quad (2.4)$$

1226 The E_T^{miss} calculation is separated into different terms based on the objects that the calorimeter clusters
 1227 are associated with. This way, each cell's contribution is calibrated appropriately according to the object.
 1228 This separation of terms used to define the E_T^{miss} in Run 1 is shown in equation 2.5 [72].

$$\begin{aligned} E_{x(y)}^{\text{miss,calo}} &= E_{x(y)}^{\text{miss},e} + E_{x(y)}^{\text{miss},\gamma} + E_{x(y)}^{\text{miss},\tau} + E_{x(y)}^{\text{miss,jets}} \\ &\quad + E_{x(y)}^{\text{miss,softjets}} + E_{x(y)}^{\text{miss},\mu} + E_{x(y)}^{\text{miss,CellOut}} \end{aligned} \quad (2.5)$$

1229 The CellOut term of the above equation corresponds to calorimeter cells with energy deposits that are
 1230 not associated with other objects. The soft jets term comes from cells associated to jets with p_T between
 1231 7 and 20 GeV, while the jets term comes from jets with $p_T > 20$ GeV. Because muons do not deposit
 1232 significant energy in the calorimeter, the muon momentum (after correction for the energy deposited in
 1233 the calorimeter for non-isolated muons) is used for the muon term [72]. The final E_T^{miss} is calculated using
 1234 equation 2.6.

$$E_T^{\text{miss}} = \sqrt{(E_x^{\text{miss}})^2 + (E_y^{\text{miss}})^2} \quad (2.6)$$

1235 Figure 2.20 shows the resolution of the components of the E_T^{miss} with different pileup suppression tech-
 1236 niques [73].

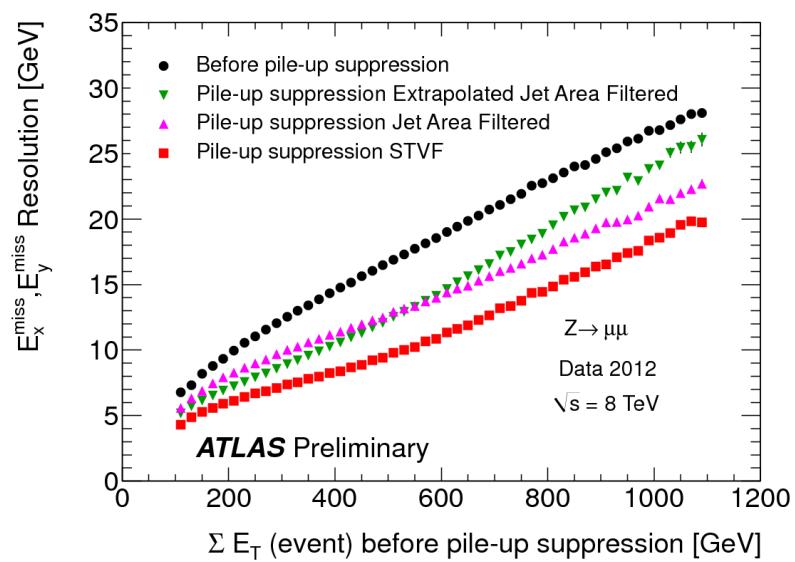

Figure 2.20: Resolution of E_T^{miss} components as a function of $\sum E_T$ before pileup suppression with different pileup techniques [73].

$H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ Analysis Strategy

1243 3.1 INTRODUCTION

1244 This chapter presents an overview of the strategy for searching for a Higgs boson in the $H \rightarrow WW^* \rightarrow$
1245 $\ell\nu\ell\nu$ decay topology. Its purpose is to define in broad terms how the search and measurement are under-
1246 taken, discussing common aspects of the analysis before going into the details of individual sub-categories.
1247 First, the properties of the Higgs signal are discussed and the associated backgrounds are presented. Next,
1248 the observables used to enhance the signal to background ratio are defined. Finally, the parameters of in-
1249 terest in the search and measurement will be shown, along with a brief overview of the statistical treatment
1250 of the final Higgs candidates.

1251 Following this chapter, three different results from the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel are shown.
1252 Chapter 4 presents the discovery and subsequent measurement of Higgs boson production in gluon fusion
1253 mode and the role of the $H \rightarrow WW^*$ channel. Chapter 5 shows the search and first evidence in ATLAS
1254 for the Vector Boson Fusion (VBF) production mode of the Higgs. Finally, chapter 6 shows the combined

1255 Run 1 $H \rightarrow WW^*$ results for the measurement of the Higgs cross section and relative coupling strengths
1256 to other SM particles.

1257 3.2 THE $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ SIGNAL IN ATLAS

1258 The signal studied in this and subsequent chapters is the Higgs boson in the WW^* final state, where each
1259 W boson subsequently decays into a charged lepton and a neutrino. In the simplest decay path, the final
1260 state consists of two neutrinos and two charged leptons, each of which can be either an electron or a muon.
1261 If a W decays to a τ lepton, only leptonic decays of the τ are considered. The τ leptons produce additional
1262 neutrinos in the final state but still yield two charged leptons (where each lepton is an electron or muon).
1263 Neutrinos are not detected in ATLAS, so the final state ultimately consists of two reconstructed leptons
1264 and missing transverse momentum. Final states where both of the charged leptons are electrons or muons
1265 are referred to as the “same flavor” ($ee/\mu\mu$) final states, while those with one electron and one muon are
1266 referred to as “different flavor” ($e\mu$ or μe).

1267 There can be additional jets produced in association with the Higgs boson. As described in detail in
1268 Chapter 1, if the Higgs is produced via vector boson fusion production, there will be two additional forward
1269 jets in the event. In gluon fusion, one or more jets can be produced through initial state radiation from
1270 the incoming gluons. Because of the varying background composition as a function of jet multiplicity,
1271 each bin in this variable has its own dedicated requirements applied in the search and measurement. The
1272 $n_j = 0$ and $n_j = 1$ bins are dedicated to gluon fusion production, while the $n_j \geq 2$ bin has separate
1273 dedicated searches for ggF and VBF production.

1274 Figure 3.1 shows the relative branching fractions for the $H \rightarrow WW^*$ process, calculated from the Par-
1275 ticle Data Group values for the W and τ branching ratios [6]. The largest branching ratio corresponds
1276 to both W bosons decaying to quark pairs at 45.44%. The second largest ratio is for one W decaying lep-
1277 tonically and the other decaying to quarks, a branching ratio of 34.18%. In all cases, ℓ denotes either an
1278 electron or muon, and the leptonic branching ratios of the τ are included. For example, the $\ell\nu qq$ final
1279 state includes one W decaying to $e\nu$, $\mu\nu$, or $\tau\nu$. In the case of the $W \rightarrow \tau\nu$ decay, the τ lepton then
1280 decays to an electron or muon via $\tau \rightarrow \nu_\tau \ell \nu_\ell$. Final states with a τ_h refer to hadronic decays of the τ . The

Figure 3.1: Branching ratios for a WW system. q refers to quarks. ℓ can be either an electron or muon, and the leptonic branching ratios of the τ are included. For example, the $\ell\nu qq$ final state includes one W decaying to $e\nu$, $\mu\nu$, or $\tau\nu$. τ_h refer to hadronic decays of the τ .

branching ratio of the $\ell\nu\ell\nu$ final state is 6.43%.

While the $\ell\nu\ell\nu$ final state is not a large fraction of the branching ratio, there are significant advantages to using this channel in an analysis. First, both the $qqqq$ and $\ell\nu qq$ channels suffer from a large QCD multijet background, which is often difficult to model. Second, events in the the $\ell\nu\ell\nu$ channel in data can be triggered more efficiently due to the presence of two leptons.

Figure 3.2 delineates the different signal regions used in the gluon fusion and vector boson fusion analyses of $H \rightarrow WW^*$. Signal regions are defined using jet multiplicity and the flavor combination of the final state leptons.

3.3 BACKGROUND PROCESSES

Many processes from the Standard Model can also produce a final state with two leptons and missing transverse momentum. This section describes the dominant backgrounds to Higgs production and further explains how they can be reduced. Table 3.1 summarizes the different background processes.

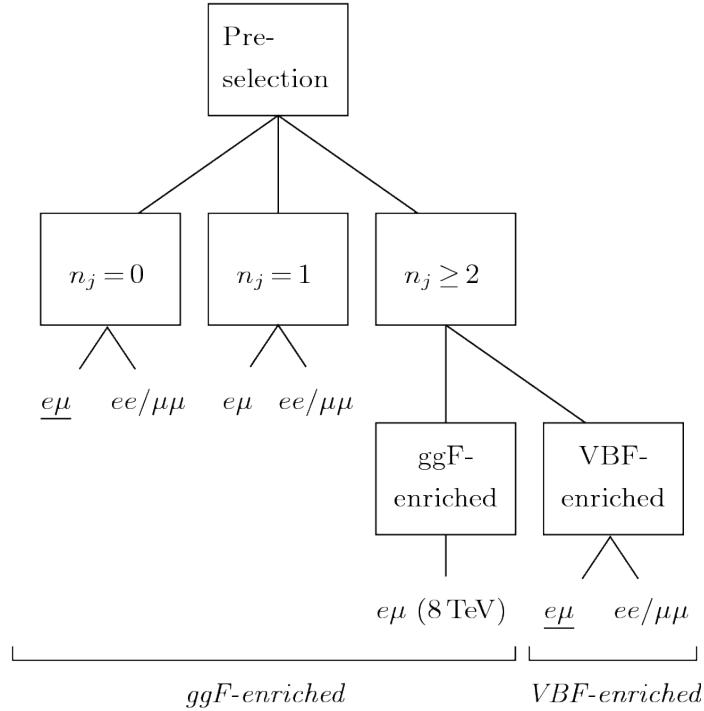

Figure 3.2: An illustration of the unique analysis signal regions [74]. The most sensitive regions for both gluon fusion and vector boson fusion production are underlined.

1293 3.3.1 STANDARD MODEL WW PRODUCTION

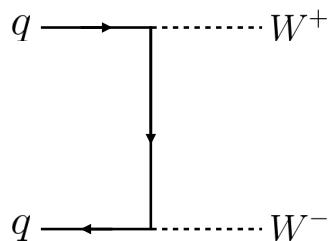

Figure 3.3: Feynman diagram for Standard Model WW production

1294 Non-resonant Standard Model diboson production, as shown in figure 3.3, is an irreducible background
1295 to Higgs boson production in the WW final state. It produces the same exact final state objects, namely
1296 leptonically decaying W bosons. There are no additional objects in the final state that allow for back-
1297 ground reduction. Therefore the analysis solely relies on the correlations between the leptons to reduce
1298 this background.

1299 3.3.2 TOP QUARK PRODUCTION

1300 Top quark production can mimic the Higgs in the WW^* final state as well. Top quarks can be produced
1301 either in pairs ($t\bar{t}$ production) or singly (s -channel, t -channel, or associated production Wt). The domi-
1302 nant top background are $t\bar{t}$ and Wt production.

1303 Because top quarks decay via $t \rightarrow Wb$, top pair production can produce a final state with two W bosons
1304 that then decay leptonically. In Wt production, there are two real W bosons produced, as with $t\bar{t}$. In
1305 both cases, there is at least one b -jet in the final state. By vetoing on the presence of b -jets, these top quark
1306 backgrounds can be reduced. Figure 3.4 shows the Feynman diagrams for $t\bar{t}$ and Wt production.

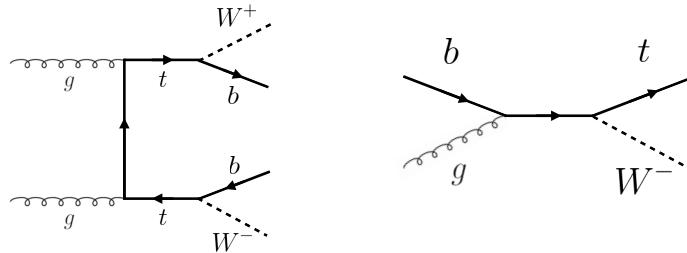

Figure 3.4: Feynman diagrams for top pair production (left) and Wt production (right)

1307 3.3.3 W +JETS BACKGROUND

1308 Single W boson production in association with jets is a unique background to Higgs production. The
1309 other backgrounds considered thus far have all included two prompt leptons, each decaying from a W
1310 boson, in the final state. In W +jets production, however, only one reconstructed lepton originates from
1311 a W . The second reconstructed lepton is either an algorithmic “fake” or the result of non-prompt decays.
1312 In the first case, the lepton is a jet misidentified as a lepton by either the electron or muon reconstruction
1313 algorithms. In the second case, the lepton may be a real lepton but coming from semi-leptonic decays of
1314 particles inside the shower of the jet. This background can be reduced by requiring that the reconstructed
1315 lepton have little activity in the surrounding region of the calorimeter (also known as an “isolation”). Fig-
1316 ure 3.5 shows the Feynman diagram for W +jets production.

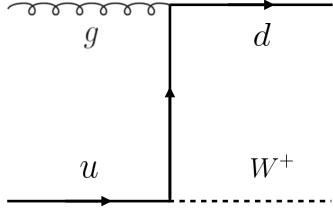

Figure 3.5: An example Feynman diagram of $W + \text{jets}$ production

1317 3.3.4 $Z/\gamma^* + \text{JETS BACKGROUND}$

1318 Production of a Z boson or virtual photon (also known as Drell-Yan and denoted with Z/γ^*) in associa-
1319 tion with jets is also a background to Higgs production. The Z boson decays to two leptons of the same
1320 flavor. However, the background is present in both the same flavor and different flavor samples. When the
1321 Z/γ^* decays directly to electrons or muons, the background enters the same flavor final state sample, and
1322 when it decays to two τ leptons the background can enter the different flavor sample as well. Figure 3.6
1323 shows the production of a Z in association with one jet. Because there are no neutrinos in this final state,
1324 variables like E_T^{miss} can be used to reduce the background¹.

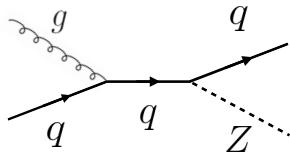

Figure 3.6: An example Feynman diagram of $Z + \text{jets}$ production

1325 3.3.5 SUBDOMINANT BACKGROUNDS

1326 There are additional processes which contribute to the background composition. These backgrounds are
1327 subdominant and contribute less to the total background estimate than those discussed previously. The

¹The E_T^{miss} cut is much more effective for the reduction of Z/γ^* production in the same flavor final state. If the background enters the different flavor final state through τ decays, there will be neutrinos present. Other requirements on the lepton invariant mass are made to reduce the $Z/\gamma^* \rightarrow \tau\tau$ background.

1328 first process is referred to as VV or “Other diboson” processes and includes multiple Standard Model
 1329 diboson processes, including WZ , ZZ , $W\gamma$, $W\gamma^*$, and $Z\gamma$ production. Additionally, there is a back-
 1330 ground contribution from QCD multijet production. While the cross section for this process is large, its
 1331 contribution to the WW^* final state is small because two jets must be misidentified as leptons.

Category	Process	Description
SM WW	$WW \rightarrow \ell\nu\ell\nu$	Real leptons and neutrinos
Top quark production	$t\bar{t} \rightarrow WbW\bar{b} \rightarrow \ell\nu b\ell\nu\bar{b}$	Real leptons, untagged b s
	$tW \rightarrow WbW \rightarrow \ell\nu\ell\nu b$	Real leptons, untagged b
	$t\bar{b}, t\bar{q}\bar{b}$	Untagged b , jet misidentified as lepton
Drell-Yan	$Z/\gamma^* \rightarrow ee, \mu\mu$	“Fake” E_T^{miss}
	$Z/\gamma^* \rightarrow \tau\tau \rightarrow \ell\nu\nu\ell\nu\nu$	Real leptons and neutrinos
Other dibosons	$ZZ \rightarrow \ell\ell\nu\nu$	Real leptons and neutrinos
	$W\gamma^*, WZ \rightarrow \ell\nu\ell\ell, ZZ \rightarrow \ell\ell\ell\ell$	Unreconstructed leptons
	$W\gamma, Z\gamma$	γ reconstructed as e , unreconstructed lepton
$W + \text{jets}$	$Wj \rightarrow \ell\nu j$	Jet reconstructed as lepton
QCD multijet	jj	Jets reconstructed as leptons

Table 3.1: A summary of backgrounds to the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ signal

1332 3.4 SHARED SIGNAL REGION SELECTION REQUIREMENTS

1333 As presented in section 3.2, there are many different combinations of physics objects that can define a
 1334 $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ final state. The multiplicity of jets and the flavor combinations of the leptons
 1335 both lead to many potential signal regions. Additionally, signal regions can be optimized separately to be
 1336 sensitive to the distinct production modes of the Higgs. Gluon fusion, vector boson fusion, and associated
 1337 production of a Higgs all lead to unique final state topologies. While there are different optimizations
 1338 possible in each signal region, there are also some commonly shared selections that will be described here.

1339 3.4.1 EVENT PRE-SELECTION

1340 Before being sorted into the distinct signal regions, basic requirements are applied to the reconstructed
 1341 objects in the event to select Higgs-like event candidates. First, two oppositely charged leptons are required.
 1342 Once the leptons are selected, the last requirement for event pre-selection is the presence of neutrinos.
 1343 E_T^{miss} is used as a proxy for the combined neutrino momentum in the transverse plane.

1344 In general, the signal tends to have higher values of E_T^{miss} than backgrounds, especially if these back-
 1345 grounds do not contain neutrinos in the final state. It is possible mis-measurements of objects in the detec-
 1346 tor can lead to imbalances in the transverse plane. When such a mis-measurement occurs, the E_T^{miss} vector
 1347 in the transverse plane will often point in the same direction as the mis-measured object. Therefore, a new
 1348 variable, $E_{T,\text{rel}}^{\text{miss}}$, is used in the pre-selection. $E_{T,\text{rel}}^{\text{miss}}$ is defined in equation 3.1.

$$E_{T,\text{rel}}^{\text{miss}} = \begin{cases} E_T^{\text{miss}} \sin \Delta\phi_{\text{near}} & \text{if } \Delta\phi_{\text{near}} < \pi/2 \\ E_T^{\text{miss}} & \text{otherwise,} \end{cases} \quad (3.1)$$

1349 If the closest object to the E_T^{miss} vector is within $\pi/2$ radians in the transverse plane, the E_T^{miss} is projected
 1350 away from this object. Otherwise, the normal E_T^{miss} vector is used. Figure 3.7 shows a graphical illustration
 of this concept.

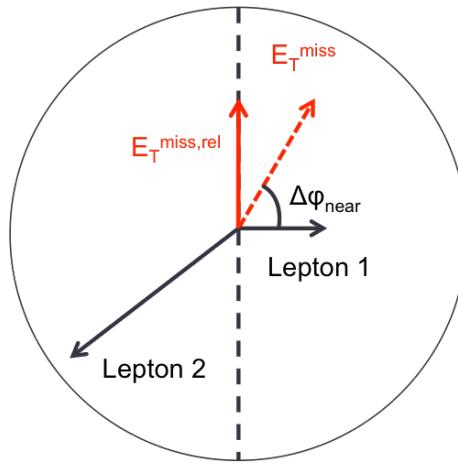

Figure 3.7: A graphical illustration of the $E_{T,\text{rel}}^{\text{miss}}$ calculation.

1351
 1352 Once the lepton and E_T^{miss} pre-selections are made, the analysis is divided into different regions accord-
 1353 ing to jet multiplicity.

1354 3.4.2 JET MULTIPLICITY

1355 Jet multiplicity, denoted as n_j , is used to sub-divide the analysis into distinct signal regions. By creating
 1356 separate signal regions, each bin in jet multiplicity becomes sensitive to different modes of Higgs produc-
 1357 tion and different backgrounds. For example, the $n_j \geq 2$ region is more sensitive to VBF production

1358 because of the two high momentum jets produced at matrix element level. For gluon fusion production
1359 to enter this bin, two initial state radiation jets must be emitted.

1360 Figure 3.8 shows the jet multiplicity in both the different flavor and same flavor regions after the pre-
1361 selection. It also shows the background composition in the bins of the number of b -tagged jets, n_b . A
1362 few trends from this distribution are worth noting. The first is that the Drell-Yan background dominates
1363 in the same flavor channels for $n_j \leq 1$. Second, the top background becomes a clear contributor to the
1364 total background for $n_j \geq 1$. Lastly, the SM WW production dominates in the $n_j = 0$ bin, as it is an
1365 irreducible background to $H \rightarrow WW^*$ production. Because of these distinct features, each jet multiplicity
1366 bin is treated separately.

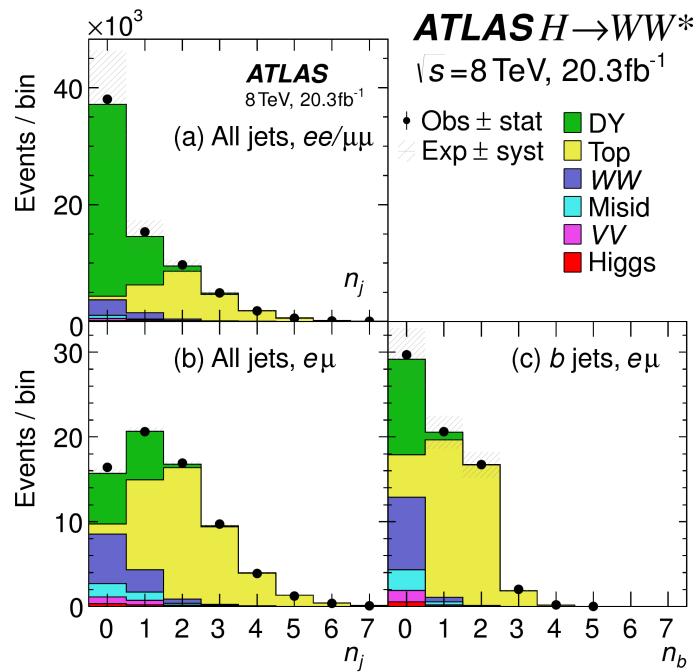

Figure 3.8: Predicted backgrounds (compared with data) as a function of the number of jets, n_j (a and b), and the number of b -tagged jets, n_b (c), after pre-selection requirements. Panel a shows n_j in the same flavor sample, while panels b and c show the n_j and n_b distributions in the different flavor sample.

1367 3.5 BACKGROUND REDUCTION IN SAME-FLAVOR FINAL STATES

1368 As described in section 3.4.2, the background composition of the same flavor final states is different from
1369 that of the different flavor states. In particular, Drell Yan processes play a much larger role because the

1370 Z/γ^* decays to same flavor leptons. Because real neutrinos are absent in the Z/γ^* decays to ee and $\mu\mu$, a
1371 requirement on E_T^{miss} should largely reduce the background. However, as this section will demonstrate,
1372 with increasing pileup conditions the resolution of the calorimeter-based E_T^{miss} degrades greatly. There-
1373 fore, two new variables for Z/γ^* background reduction are constructed and described in this section.

1374 **3.5.1 PILEUP AND E_T^{miss} RESOLUTION**

1375 Secondary interactions of protons in the colliding bunches of the LHC (known as pileup interactions,
1376 described in detail in Chapter 2) deposit energy into the ATLAS calorimeter in addition to the energy that
1377 comes from the hard scatter process of interest. The calculation of E_T^{miss} is fundamentally like a Poisson
1378 process - summing up all of the energy deposits in individual calorimeter cells or clusters is similar to a
1379 counting experiment. The error on a mean of N in a Poisson distribution is \sqrt{N} , so the energy resolution
1380 scales as \sqrt{E} . As more energy is deposited in the calorimeter, the E_T^{miss} resolution degrades, meaning that
1381 the E_T^{miss} resolution is particularly sensitive to LHC instantaneous luminosity conditions.

1382 Figure 3.9 shows an event display of a $Z/\gamma^* + \text{jets}$ event candidate with the twenty-five reconstructed
1383 primary vertices. This display illustrates that while the interaction of interest only has tracks coming from
1384 the hardest primary vertex, all of the secondary interactions deposit energy in the calorimeter as well.

1385 Figure 3.10 shows the RMS of the E_T^{miss} distribution in $Z \rightarrow \mu\mu$ events (where there are no real neu-
1386 trinos) as a function of the number of the average number of interactions. Under 2011 LHC conditions,
1387 this RMS was approximately 9 GeV, while under 2012 running conditions the resolution worsened to 12
1388 GeV. The increase in pileup dilutes the ability of the E_T^{miss} variable to reduce the Z/γ^* background.

1389 **3.5.2 TRACK-BASED DEFINITIONS OF MISSING TRANSVERSE MOMENTUM**

1390 Because the increasing number of secondary proton-proton interactions degrades calorimeter-based E_T^{miss}
1391 resolution, a new variable using only contributions from the primary interaction vertex is necessary to
1392 further reduce the Z/γ^* background. While it is not possible to associate calorimeter energy deposits
1393 with a particular vertex, individual charged particle tracks in the Inner Detector are associated to unique
1394 vertices. Thus, two track-based definitions of missing transverse momentum, using only tracks coming

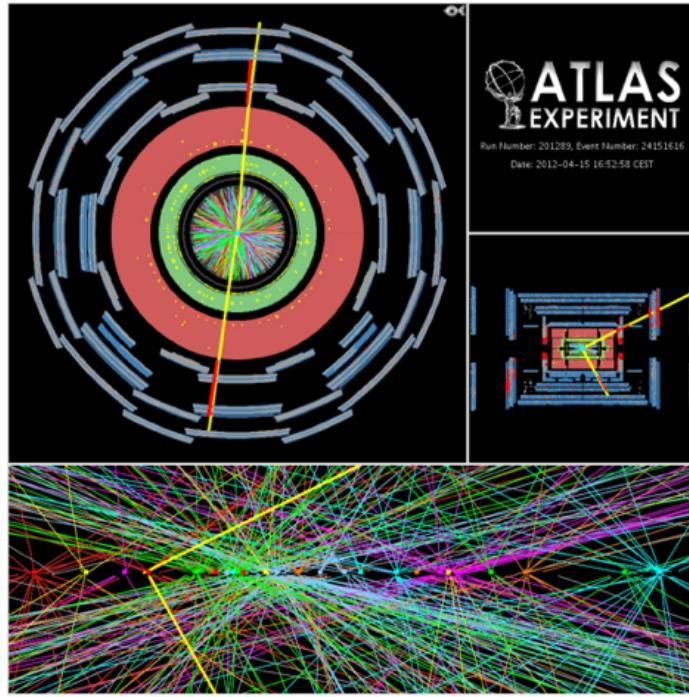

Figure 3.9: An event display of a $Z/\gamma^* + \text{jets}$ event illustrating the effect of pileup interactions

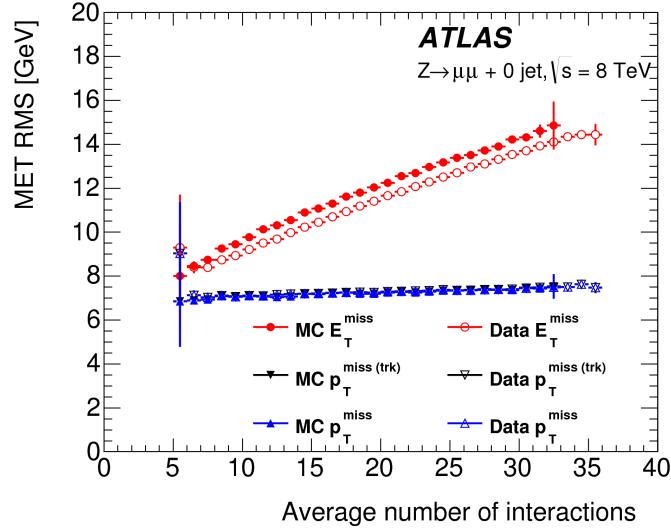

Figure 3.10: The RMS of different missing transverse momentum definitions as a function of the average number of interactions per bunch crossing

from the primary vertex in the event, are used in the analysis. These variables are not intended to substitute E_T^{miss} , as they only account for charged particles and do not measure neutrals. However, the track-based variables serve as a confirmation that any measured momentum imbalance is coming from real particles

1398 and not detector effects. The simplest variable, $p_T^{\text{miss}(\text{trk})}$, is the vectorial sum of the p_T of all of the tracks
 1399 from the primary vertex and the selected leptons (excluding the tracks associated with the selected leptons
 1400 to avoid double counting). Equation 3.2 defines $p_T^{\text{miss}(\text{trk})}$.

$$p_T^{\text{miss}(\text{trk})} = - \left(\sum_{\text{selected leptons}} p_T + \sum_{\text{other tracks}} p_T \right), \quad (3.2)$$

1401 To further improve the resolution on the missing transverse momentum, the variable p_T^{miss} is used as de-
 1402 fined in equation 3.3. For selected leptons and jets, the nominal p_T measurements are used, as the calorime-
 1403 ter information improves the p_T resolution of the objects by taking into account the presence of neutral
 1404 particles in showers. The soft component of the missing transverse momentum, which is more suscep-
 1405 tible to spurious contributions from pileup interactions, is estimated using tracks instead of calorimeter
 1406 measurements.

$$p_T^{\text{miss}} = - \left(\sum_{\text{selected leptons}} p_T + \sum_{\text{selected jets}} p_T + \sum_{\text{other tracks}} p_T \right), \quad (3.3)$$

1407 Figure 3.10 illustrates that these two new variables accomplish their intended purpose. The resolution as a
 1408 function of mean number of interactions for both $p_T^{\text{miss}(\text{trk})}$ and p_T^{miss} is much flatter than the dependence
 1409 for E_T^{miss} . Figure 3.IIA shows the difference between the true and reconstructed values of missing transverse
 1410 momentum using both the track-based p_T^{miss} and calorimeter based E_T^{miss} . The RMS of the distribution
 1411 improves by 3.5 GeV when using p_T^{miss} .

1412 3.5.3 DISTINGUISHING Z/γ^* +JETS AND $H \rightarrow WW^*$ TOPOLOGIES

1413 In addition to measuring missing transverse momentum, another variable can be constructed to exploit
 1414 kinematic and topological differences between the Z/γ^* background and $H \rightarrow WW^*$ signal. Because
 1415 there are no real neutrinos in the final state (in the case of $Z/\gamma^* \rightarrow ee, \mu\mu$ decays), the dilepton system
 1416 will be balanced with the jets produced in the hard scatter. A new variable, f_{recoil} , is constructed to es-
 1417 timate the balance between the dilepton system and recoiling jets and is defined in equation 3.4. The
 1418 transverse plane is divided into four sections, or quadrants, with one quadrant centered on the dilepton

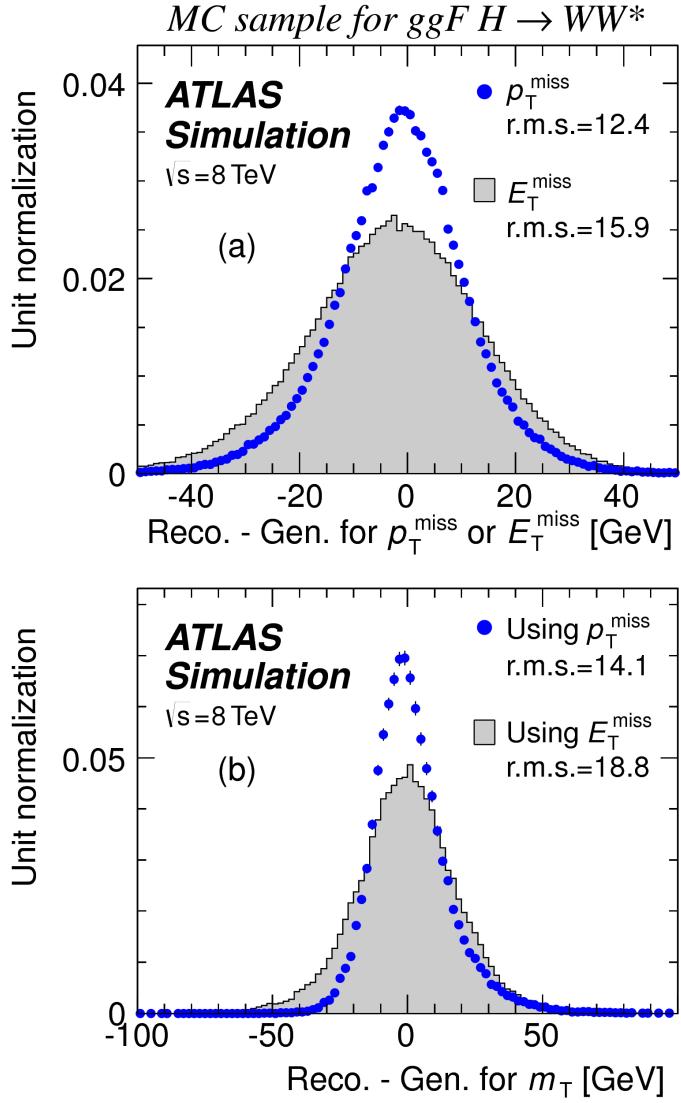

Figure 3.II: The difference between the true and reconstructed values of the missing transverse momentum (a) and m_T (b) in a gluon fusion signal sample using both track-based (p_T^{miss}) and calorimeter-based E_T^{miss} definitions.

¹⁴¹⁹ vector. The numerator of f_{recoil} is the magnitude of the vectorial sum of the p_T of jets in the quadrant
¹⁴²⁰ opposite the dilepton system, weighted the Jet Vertex Fraction (JVF, described in chapter 2) of each jet.
¹⁴²¹ The denominator is the magnitude of the dilepton p_T .

$$f_{\text{recoil}} = \left| \sum_{\text{jets } j \text{ in } \wedge} \text{JVF}_j \cdot \mathbf{p}_T^j \right| / p_T^{\ell\ell}. \quad (3.4)$$

1422 Figure 3.12 shows a shape comparison of the f_{recoil} distribution in a simulated $Z/\gamma^* + \text{jets}$ sample, a
 1423 $H \rightarrow WW^*$ signal sample, and other backgrounds that contain real neutrinos. The $Z/\gamma^* + \text{jets}$ events
 1424 tend to be more balanced between the dilepton system and recoiling jets, while the processes containing
 1425 real neutrinos are less balanced in the transverse plane. Thus, a requirement on f_{recoil} will reduce the Z/γ^*
 1426 + jets background while maintaining a good signal efficiency.

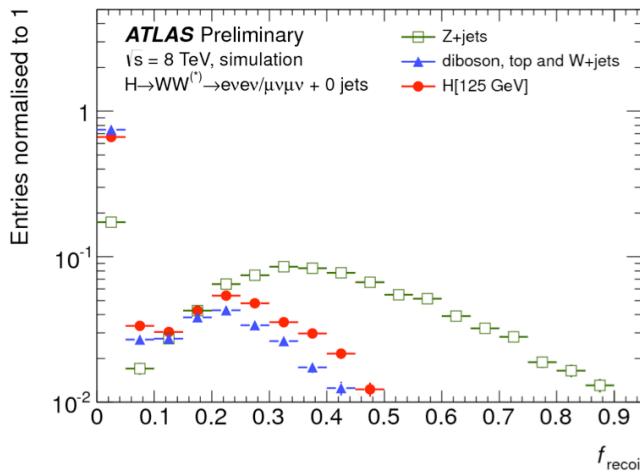

Figure 3.12: Comparison of f_{recoil} distributions for $Z/\gamma^* + \text{jets}$, $H \rightarrow WW^*$, and other backgrounds with real neutrinos.

1427 3.5.4 OPTIMIZING BACKGROUND REDUCTION SELECTION REQUIREMENTS

1428 The requirements on $p_T^{\text{miss}(\text{trk})}$ and f_{recoil} used to reduce the $Z + \text{jets}$ background must be optimized to
 1429 maximize expected signal significance in the same flavor channels. Figure 3.13 shows an optimization of the
 1430 combination of the two requirements in the gluon fusion zero jet bin. Each bin shows the expected signal
 1431 significance if the $p_{T,\text{rel}}^{\text{miss}(\text{trk})}$ (the track-based version of $E_{T,\text{rel}}^{\text{miss}}$) is required to be greater than the left edge
 1432 of the bin and the f_{recoil} is required to be less than the top edge of the bin. The figure shows that the best
 1433 signal significance comes from requiring low values of f_{recoil} (< 0.05) and $p_{T,\text{rel}}^{\text{miss}(\text{trk})}$ values greater than
 1434 45 GeV.

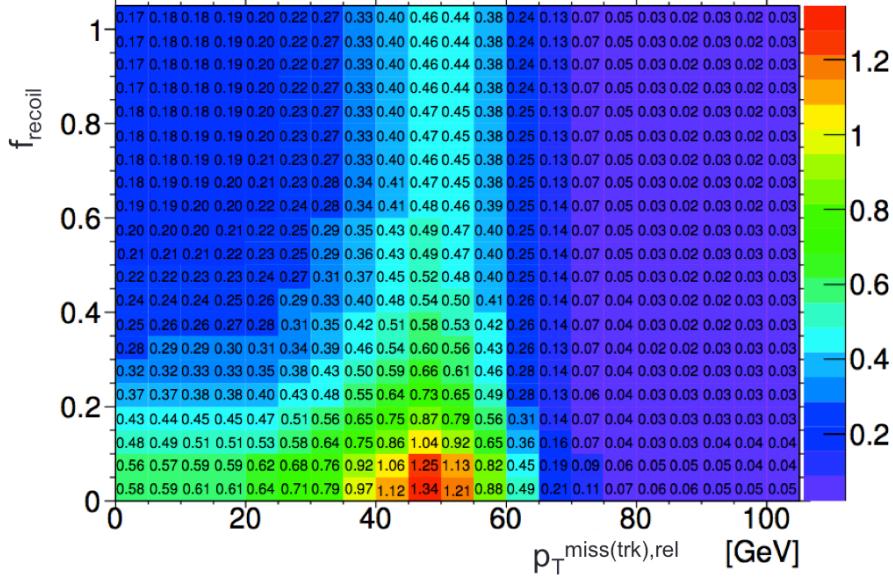

Figure 3.13: Signal significance as a function of required value for f_{recoil} and $p_{T,\text{rel}}^{\text{miss}(\text{trk})}$ in the ggF $H \rightarrow WW^*$ with $n_j = 0$

1435 3.6 PARAMETERS OF INTEREST AND STATISTICAL TREATMENT

1436 As with any search or measurement, there are particular parameters of the Higgs that the $H \rightarrow WW^*$
 1437 analysis is interested in measuring. In this case, the parameters of interest are the mass of the Higgs boson
 1438 and its production cross section. In the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ final state, it is not possible to measure
 1439 the full invariant mass of the Higgs due to the presence of neutrinos. However, a proxy for the invariant
 1440 mass is defined using transverse plane information and detailed in section 3.6.1. The second parameter of
 1441 interest is the cross section σ , which in this analysis is measured relative to the theoretical prediction for a
 1442 Standard Model Higgs. This ratio, μ , is defined in equation 3.5.

$$\mu = \frac{\sigma}{\sigma_{\text{SM}}} \quad (3.5)$$

1443 All of the likelihoods used in the statistical analysis of the final signal region events are parameterized as a
 1444 function of μ . μ is a natural variable for hypothesis testing, as $\mu = 0$ corresponds to a background only
 1445 hypothesis and $\mu = 1$ corresponds exactly to a Standard Model Higgs.

1446 3.6.1 TRANSVERSE MASS

1447 The $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis cannot reconstruct the full invariant mass of the Higgs because of the
1448 neutrinos in the final state. The transverse mass serves as a proxy for the full invariant mass by exploiting
1449 information from the transverse plane. The transverse mass is defined in equation 3.6.

$$m_T = \sqrt{(E_T^{\ell\ell} + p_T^{\text{miss}})^2 - |\vec{p}_T^{\ell\ell} + \vec{p}_T^{\text{miss}}|^2}, \quad (3.6)$$

1450 Here the $E_T^{\ell\ell}$ and $p_T^{\ell\ell}$ are the transverse energy and momentum of the dilepton system, while p_T^{miss} is a
1451 proxy for the transverse momentum of the di-neutrino system. The track-based p_T^{miss} is used in the m_T
1452 rather than the calorimeter based E_T^{miss} because it has a better resolution on the true transverse mass.
1453 Figure 3.11b shows the improvement in the RMS of the difference between the true and reconstructed
1454 transverse mass in a ggF signal sample. The RMS improves by 4.7 GeV using p_T^{miss} in the m_T calculation.

1455 3.6.2 STATISTICAL TREATMENT

1456 LIKELIHOOD FUNCTION

1457 The statistical analysis² of final event candidates is framed as a hypothesis test, where the null hypothesis is
1458 background-only (no Standard Model Higgs). The first step in the analysis is to form a likelihood function
1459 for the data. In its simplest form, this likelihood is the probability of observing the number of events seen
1460 in the final signal region given knowledge of the signal strength. Because observation of events is funda-
1461 mentally a Poisson counting experiment, this simple likelihood can be expressed as a Poisson probability of
1462 observing N events given a total number of predicted signal and background events. This basic likelihood
1463 is shown in equation 3.7.

$$\mathcal{L}(\mu) = P(N|\mu S + B) \quad (3.7)$$

1464 Here, P is the Poisson probability density function, N is the total number of observed events, μ is the
1465 signal strength, S is the predicted number of signal events, and B is the predicted number of background
1466 events.

²Many thanks to Aaron Armbruster, whose thesis [75] inspired parts of this section.

1467 Generally, in searches, certain background estimates are commonly normalized in so-called “control” re-
 1468 gions and those predictions are scaled by the same normalization factor in the signal region. This method
 1469 allows for more precise background estimation by using data as a constraint, reducing the impact of theo-
 1470 retical uncertainties on the background model. This leads to a slightly more complicated likelihood, which
 1471 is a function of both the signal strength and the background normalization. This is shown in equation 3.8.
 1472

$$\mathcal{L}(\mu, \theta) = P(N|\mu S + \theta B) P(N_{\text{CR}}|\theta B_{\text{CR}}) \quad (3.8)$$

1473 Here, θ serves as a “nuisance parameter”, or a parameter that is not of primary interest but still enters the
 1474 likelihood. The second Poisson term enforces that the background normalization be consistent with the
 1475 number of observed events in data in the control region, N_{CR} .

1476 So far, these two formulations of likelihoods have assumed a single signal region and do not take into
 1477 account any shape information of potential discriminating variables. The $H \rightarrow WW^*$ analysis is divided
 1478 into many different categories, and the counting experiment described above can be performed in each
 1479 individual category. As mentioned in section 3.6.1, the transverse mass is used as the primary discriminating
 1480 variable in many of the $H \rightarrow WW^*$ signal regions. The same counting experiment can be performed
 1481 in each bin of the m_T distribution to incorporate some shape information. Thus, the total likelihood
 1482 becomes a product over signal regions and bins of the m_T distribution. Finally, there are usually many
 1483 background sources that are normalized in control regions. The new formulation of the likelihood takes
 1484 this into account by including a product over control regions in the second Poisson term. All of these
 1485 modifications are shown in equation 3.9.

$$\mathcal{L}(\mu, \theta) = \prod_{\substack{\text{SRs } i \\ \text{bins } b}} P\left(N_{ib} \middle| \mu S_{ib} + \sum_{\text{bkg } k} \theta_k B_{kib}\right) \prod_{\text{CRs } l} P\left(N_l \middle| \sum_{\text{bkg } k} \theta_k B_{kl}\right) \quad (3.9)$$

1486 Here, the variable i counts over the different signal regions, b counts over bins of m_T , k counts over the
 1487 backgrounds, and l counts over the control regions.

1488 The final step to obtain the full likelihood used in the analysis is to add nuisance parameters for the
 1489 systematic uncertainties. In cases where the uncertainty does not affect the shape of m_T bin-by-bin, each

systematic uncertainty ϵ is allowed to affect the expected event yields through a linear response function of the nuisance parameter, namely $\nu(\theta) = (1 + \epsilon)\theta$. If instead the uncertainty does affect the shape, the effect is instead parameterized by $\nu_b(\theta) = 1 + \epsilon_b\theta$. The value of the nuisance parameters for the systematic uncertainty are constrained with a Gaussian term that is added to the likelihood as well. This is of the form $g(\delta|\theta) = e^{-(\delta-\theta)^2/2}/\sqrt{2\pi}$, where δ is the central value and θ is a nuisance parameter. Finally, a last term is added to account for the statistical uncertainty in the Monte Carlo samples used, which adds an additional poisson term. The full likelihood used in the final statistical analysis is defined in equation 3.10.

$$\begin{aligned}
 \mathcal{L}(\mu, \boldsymbol{\theta}) = & \prod_{\substack{\text{SRs i} \\ \text{bins b}}} P \left(N_{ib} \middle| \mu S_{ib} \cdot \prod_{\substack{\text{sig.} \\ r}} \nu_{br}(\theta_r) + \sum_{\text{bkg k}} \theta_k B_{kib} \cdot \prod_{\substack{\text{bkg.} \\ s}} \nu_{bs}(\theta_s) \right) \\
 & \cdot \prod_{\text{CRs l}} P \left(N_l \middle| \sum_{\text{bkg k}} \theta_k B_{kl} \right) \\
 & \cdot \prod_{\substack{\text{syst} \\ t}} g(\delta_t|\theta_t) \cdot \prod_{\text{bkg k}} P(\xi_k|\zeta_k\theta_k)
 \end{aligned} \tag{3.10}$$

Here, $\boldsymbol{\theta}$ represents the full vector of nuisance parameters, r is an index for signal systematics, s is an index for background systematics, and t is an index for Monte Carlo samples. The fourth term of the equation quantifies the uncertainty due to finite Monte Carlo sample size. Here, ξ represents the central value of the background prediction, θ is the associated nuisance parameter, $\zeta = (B/\delta B)^2$, where δB is the statistical uncertainty of B .

The best fit value of the signal strength μ is determined by finding the values of μ and $\boldsymbol{\theta}$ that maximize the likelihood, while setting $\delta = 0$ and $\xi = \zeta$. Once the likelihood is defined, a test statistic must be built for use in hypothesis testing.

TEST STATISTIC

To distinguish whether the data match a background only or background and signal hypothesis, a test statistic must be used. The $H \rightarrow WW^*$ analysis uses the profile likelihood technique [76]. The first step

1508 in formulating this test statistic is to define the profile likelihood ratio, shown in equation 3.11.

$$\lambda(\mu) = \frac{\mathcal{L}(\mu, \hat{\theta}_\mu)}{\mathcal{L}(\hat{\mu}, \hat{\theta})} \quad (3.11)$$

1509 Here $\hat{\theta}_\mu$ is the value of θ that maximizes the likelihood for the choice of μ being tested. Additionally, $\hat{\theta}$
1510 and $\hat{\mu}$ represent the values of θ and μ that gives the overall maximum value of the likelihood.

1511 Once this is defined, a test statistic q_μ is constructed. This is shown in equation 3.12.

$$q_\mu = -2 \ln \lambda(\mu) \quad (3.12)$$

1512 A higher value of q_μ indicates that the data are more incompatible with the hypothesized value of μ , and
1513 q_0 then corresponds to the value of the test statistic for the background only hypothesis. A p_0 value is
1514 then defined to quantify the compatibility between the data and the null hypothesis. The p_0 value is the
1515 probability of obtaining a value of q_0 larger than the observed value, and this is shown in equation 3.13.

$$p_0 = \int_{q_0^{\text{obs}}}^{\infty} f(q_\mu | \mu = 0) dq_\mu \quad (3.13)$$

1516 Here $f(q_\mu)$ is the probability distribution function of the test statistic. Finally, the p_0 value can be con-
1517 verted into a signal significance, using the formula in equation 3.14, or the one-sided tail of the Gaussian
1518 distribution.

$$Z_0 = \sqrt{2} \operatorname{erf}^{-1}(1 - 2p_0) \quad (3.14)$$

1519 The threshold for discovery used in particle physics is $Z_0 \geq 5$, more commonly known as a value of 5σ .

The real voyage of discovery consists not in seeking new landscapes, but in having new eyes.

1521 The discovery of the Higgs boson and the role 1522 of the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel

1523 4.1 INTRODUCTION

1524 This chapter presents the results of the search for the Higgs boson in 4.8 fb^{-1} collected at $\sqrt{s} = 7 \text{ TeV}$
1525 and 5.8 fb^{-1} at $\sqrt{s} = 8 \text{ TeV}$. The results of three searches at $\sqrt{s} = 8 \text{ TeV}$ in the $H \rightarrow WW^* \rightarrow$
1526 $\ell\nu\ell\nu$, $H \rightarrow \gamma\gamma$, and $H \rightarrow ZZ \rightarrow 4\ell$ channels are shown. These results at 8 TeV are combined
1527 with the results of searches at $\sqrt{s} = 7 \text{ TeV}$ in the same channels along with $H \rightarrow \tau\tau$ production and
1528 associated production searches for $H \rightarrow b\bar{b}$. The results of this combination are a 5.9σ detection of a
1529 new particle consistent with a Higgs boson produced via gluon fusion. Rather than going into detail for
1530 all of the different Higgs decay searches, this chapter will discuss the three most sensitive channels and in
1531 particular focus on $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$. While the focus is on WW^* , some of the ZZ^* and $\gamma\gamma$ results

1532 are shown for completeness. The results not discussed here can be found in the ATLAS Higgs discovery
1533 publication [1].

1534 **4.2 DATA AND SIMULATION SAMPLES**

1535 The data sample used for the following results was taken in 2011 and 2012 at center of mass energies of 7 and
1536 8 TeV, respectively, with 4.8 fb^{-1} collected at 7 TeV and 5.8 fb^{-1} collected at 8 TeV. Higgs production
1537 in the gluon fusion and vector boson fusion modes is modeled with POWHEG for the hard scattering event
1538 and PYTHIA for the showering and hadronization. Associated production of a Higgs with a vector boson
1539 or top quarks is modeled via PYTHIA . Table 4.1 shows the Monte Carlo generators used for modeling the
1540 signal and background processes relevant for the three analyses to be discussed.

Process	Generator
ggF, VBF H	POWHEG + PYTHIA
$WH, ZH, t\bar{t}H$	PYTHIA
$W + \text{jets}, Z/\gamma^* + \text{jets}$	ALPGEN + HERWIG
$t\bar{t}, tW, tb$	MC@NLO + HERWIG
tqb	ACERMC + PYTHIA
$q\bar{q} \rightarrow WW$	MC@NLO + HERWIG
$gg \rightarrow WW$	GG2WW+ HERWIG
$q\bar{q} \rightarrow ZZ$	POWHEG + PYTHIA
$gg \rightarrow ZZ$	GG2ZZ+ HERWIG
WZ	MADGRAPH+ PYTHIA , HERWIG
$W\gamma + \text{jets}$	ALPGEN + HERWIG
$W\gamma^*$	MADGRAPH+ PYTHIA
$q\bar{q}/gg \rightarrow \gamma\gamma$	SHERPA

Table 4.1: Monte carlo generators used to model signal and background for the Higgs search [1].

1541 **4.3 $H \rightarrow WW \rightarrow e\nu\mu\nu$ SEARCH**

1542 The $H \rightarrow WW \rightarrow e\nu\mu\nu$ search is unique compared to the ZZ and $\gamma\gamma$ channels. The Higgs mass
1543 cannot be fully reconstructed due to the presence of neutrinos in the final state, so the transverse mass m_T
1544 is used as the final discriminating variable. This channel also has a wider variety of backgrounds compared
1545 to other channels, as discussed in chapter 3. The same flavor final states are excluded from the 8 TeV dataset

1546 due to high pileup conditions¹. These final states are later included in results with the full Run 1 dataset,
1547 as discussed in chapters 5 and 6.

1548 **4.3.1 EVENT SELECTION**

1549 The analysis requires to opposite charge isolated leptons, with the leading (sub-leading) lepton required to
1550 have $p_T > 25(15)$ GeV. The events are separated into different signal regions depending on which flavor
1551 of lepton is leading ($e\mu$ for leading electron, μe for leading muon). Strict lepton quality cuts are applied
1552 to the sample to reduce backgrounds from mis-reconstructed leptons.

1553 Jets are reconstructed with the anti- k_T algorithm with a radius parameter $R = 0.4$. The jets are re-
1554 quired to have $p_T > 25$ GeV and $|\eta| < 4.5$, with jets in the tracking volume required to have a jet vertex
1555 fraction of 0.5 and jets in the forward region required to have $p_T > 30$ GeV. The analysis is separated
1556 into three different signal regions based on jet multiplicity: $n_j = 0, 1, \geq 2$.

1557 To indicate the presence of neutrinos in the event, a requirement of $E_{T,\text{rel}}^{\text{miss}} > 25$ GeV is made². This
1558 requirement significantly reduces the QCD multijet and Z/γ^* + jets backgrounds. Figure 4.1 shows the
1559 distribution of n_j in data and simulation after applying these “pre-selection” requirements.

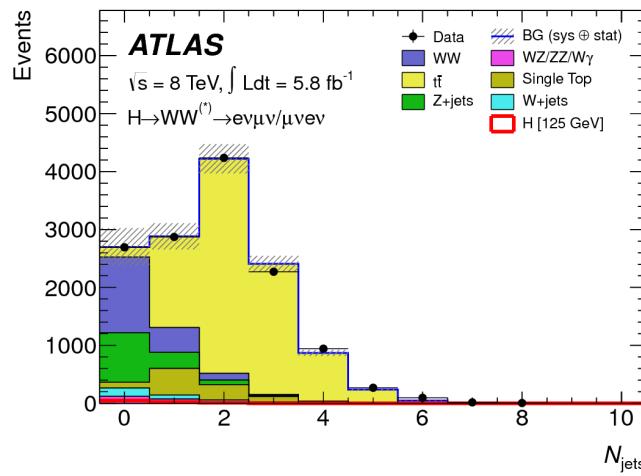

Figure 4.1: Jet multiplicity distribution in data and MC after applying lepton, jet, and $E_{T,\text{rel}}^{\text{miss}}$ selections. The WW and top backgrounds have been normalized using control samples, and the hashed band indicates the total uncertainty on the prediction [1].

¹The less sensitive 7 TeV search result includes both different flavor and same flavor final states.

²For the definition of $E_{T,\text{rel}}^{\text{miss}}$, see section 3.4.1.

1560 Additional selections are applied to require the dilepton topology to correspond to that of a Standard
1561 Model Higgs boson. The requirements are presented here - more detailed discussion on the motivation
1562 for each requirement is saved for Chapter 5. In all of the jet multiplicity channels, the dilepton system
1563 is required to have a small gap in azimuthal angle, $\Delta\phi_{\ell\ell} < 1.8$. Similarly, the dilepton invariant mass,
1564 $m_{\ell\ell}$, is required to be less than 50 GeV in the lower jet multiplicity channels and less than 80 GeV in the
1565 $n_j \geq 2$ channel. In the $n_j = 0$ channel, the magnitude of the dilepton p_T , $p_T^{\ell\ell}$, is required to be greater
1566 than 30 GeV.

1567 In the higher jet multiplicity channels ($n_j \geq 1$), the top background is a larger fraction of the total
1568 background and must be reduced more carefully. The total transverse momentum p_T^{sum} is thus required
1569 to be less than 30 GeV. Additionally, the di- τ invariant mass $m_{\tau\tau}$ (dilepton mass computed under the
1570 assumption that the neutrinos from the τ decay are emitted collinear to the charged leptons [77]) is used
1571 to reject $Z \rightarrow \tau\tau$ events by requiring $|m_{\tau\tau} - m_Z| > 25$ GeV. These variables are also discussed in more
1572 detail in Chapter 5.

1573 In the $n_j \geq 2$ channel, requirements are made to isolate the VBF contribution to Higgs production.
1574 The kinematics of the two leading jets are used to make these requirements. In particular, the event must
1575 have $\Delta y_{jj} > 3.8$ and $m_{jj} > 500$ GeV, along with a veto on having any additional jets with rapidity
1576 between the two leading jets.

1577 4.3.2 BACKGROUND ESTIMATION

1578 The details of the background estimation techniques used in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis are
1579 discussed in section 5.5. The dominant backgrounds are SM WW production and top (both pair and
1580 single) production, and these backgrounds have their normalizations estimated from dedicated control
1581 regions while their shapes are taken from simulation.

1582 The control sample for the Standard Model WW background is defined by making the same require-
1583 ments as the signal region with the $m_{\ell\ell}$ requirement inverted (now requiring $m_{\ell\ell} > 80$ GeV) and remov-
1584 ing the $\Delta\phi_{\ell\ell}$ requirement. This creates a control sample that is 70% (40%) pure in the 0(1)-jet region. The
1585 correction to the pure MC-based background estimate is quantified by defining a normalization factor β

1586 which is the ratio of the data yield to the MC yield ($N_{\text{data}}/N_{\text{MC}}$) in this control sample. Table 4.2 shows
 1587 the WW normalization factors in the $n_j = 0$ and $n_j = 1$ bins (the $n_j \geq 2$ estimate is taken directly
 1588 from MC).

n_j	β_{WW}	β_t
= 0	1.06 ± 0.06	1.11 ± 0.06
= 1	0.99 ± 0.15	1.11 ± 0.05
≥ 2	-	1.01 ± 0.26

Table 4.2: Normalization factors (ratio of data and MC yields in a control sample) for the Standard Model WW and top backgrounds in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis [1]. Only statistical uncertainties are shown.

1589 The top background estimate is also computed separately in each jet multiplicity bin. In the $n_j = 0$
 1590 channel, the background is first normalized using data after pre-selection requirements with no selection
 1591 on n_j . Then, a dedicated b -tagged control sample is used to evaluate the ratio of one-jet to two-jet events in
 1592 data. The details of this technique are shown in reference [78]. In the $n_j = 1$ and the $n_j \geq 2$ regions, the
 1593 top background is normalized in a control sample where the signal region selections are applied, but the
 1594 b -jet veto is reversed and the Higgs topology requirements on $m_{\ell\ell}$ and $\Delta\phi_{\ell\ell}$ are removed. The resulting
 1595 normalization factors for these techniques are shown in table 4.2.

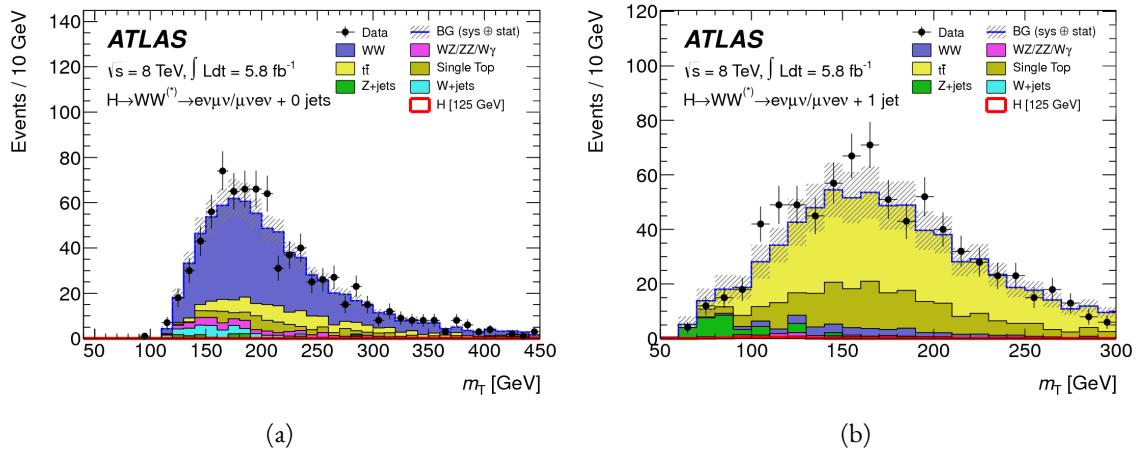

Figure 4.2: Comparison of m_T between data and simulation in the $n_j = 0$ WW (a) and $n_j = 1$ top (b) control samples [1].

1596 The control samples which are used for background normalization can also be used to validate the mod-
 1597 eling of the m_T distribution for each background. Figure 4.2 shows the comparison between data and MC

1598 for the m_T distribution after correcting the normalization of the backgrounds in the WW and top control
1599 regions. Good agreement between data and simulation is seen in both cases.

1600 The $W + \text{jets}$ background estimate is taken entirely from data using a control sample with one well recon-
1601 structed lepton and one anti-identified lepton. All other backgrounds are taken purely from simulation.

1602 4.3.3 SYSTEMATIC UNCERTAINTIES

1603 The systematic uncertainties that have the largest impact on the analysis are the theoretical uncertainties
1604 associated with the signal cross section. These are shared with the ZZ^* and $\gamma\gamma$ channels. The uncertainties
1605 resulting from variations of the QCD scale are $+7\% / -8\%$ on the final signal yield. Those coming from
1606 variations of the parton distribution function (PDF) used in the simulation add a $\pm 8\%$ uncertainty on
1607 the yield. The uncertainties on the branching ratios of the Higgs are $\pm 5\%$.

1608 The main experimental uncertainties come from variations of the jet energy scale (JES), jet energy reso-
1609 lution, pile-up, E_T^{miss} , b -tagging efficiency, $W + \text{jets}$ background estimate, and integrated luminosity. For
1610 more details, see reference [1].

1611 4.3.4 RESULTS

1612 Table 4.3 shows the signal and background yields in the final signal region after normalizing the back-
1613 grounds according to the methods described above.

	$n_j = 0$	$n_j = 1$	$n_j \geq 2$
Signal	20 ± 4	5 ± 2	0.34 ± 0.07
WW	101 ± 13	12 ± 5	0.10 ± 0.14
Other dibosons	12 ± 3	1.9 ± 1.1	0.10 ± 0.10
$t\bar{t}$	8 ± 2	6 ± 2	0.15 ± 0.10
Single top	3.4 ± 1.5	3.7 ± 1.6	-
$Z/\gamma^* + \text{jets}$	1.9 ± 1.3	0.10 ± 0.10	-
$W + \text{jets}$	15 ± 7	2 ± 1	-
Total background	142 ± 16	26 ± 6	0.35 ± 0.18
Observed in data	185	38	0

Table 4.3: Data and expected yields for signal and background in the final $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ signal region.
Uncertainties shown are both statistical and systematic [1].

1614 Figure 4.3 shows the m_T distribution in the $n_j \leq 1$ channels for 8 TeV data. (No events are observed
 1615 in data in the $n_j \geq 2$ channels in this dataset). The excess shown here relatively flat as a function of
 1616 hypothesized Higgs mass. The combined 7 and 8 TeV data gives an excess with local significance of 2.8σ
 1617 with an expected significance of 2.3σ , corresponding to a μ measurement of 1.3 ± 0.5 .

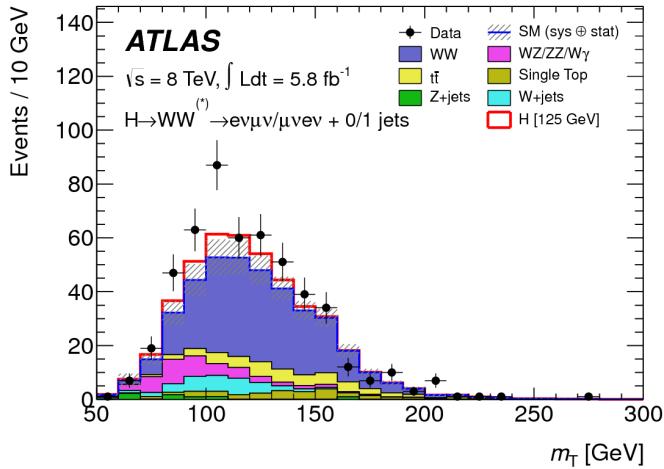

Figure 4.3: m_T distribution in the $H \rightarrow WW \rightarrow e\nu\mu\nu$ $n_j \leq 1$ channels for 8 TeV data [1].

1618 4.4 $H \rightarrow \gamma\gamma$ SEARCH

1619 The $H \rightarrow \gamma\gamma$ search is a search for a peaked excess above the falling SM diphoton mass spectrum, with
 1620 $m_{\gamma\gamma}$ as the ultimate discriminating variable. Events are selected by requiring two isolated photons, with
 1621 the leading (sub-leading) photon required to have $E_T > 40(30)$ GeV. In the 8 TeV data, the photons are
 1622 required to pass identification criteria consistent with a photonic shower in the electromagnetic calorimeter
 1623 and little leakage in the hadronic calorimeter.

1624 The main challenges for this analysis are accurate mass reconstruction and background estimation. In
 1625 order to accurately reconstruct the invariant mass of the di-photon system, both the energy and direction
 1626 of the photons must be measured well. Therefore, the identification of the primary vertex of the hard
 1627 interaction is particularly important, and is done using a multivariate likelihood which combines informa-
 1628 tion about the photon direction and vertex position. The background is modeled with a falling spectrum
 1629 in $m_{\gamma\gamma}$ that is parameterized by different functions depending on the category of the event.

1630 4.4.1 RESULTS

1631 The resulting diphoton mass spectrum is shown in figure 4.4. The best fit mass value in the $\gamma\gamma$ channel
 1632 alone in the combined 7 and 8 TeV data is 126.5 GeV. The local significance at this point is 4.5σ , with
 1633 an expected significance of 2.5σ . Therefore, the measured signal strength μ is 1.8 ± 0.5 in this channel.

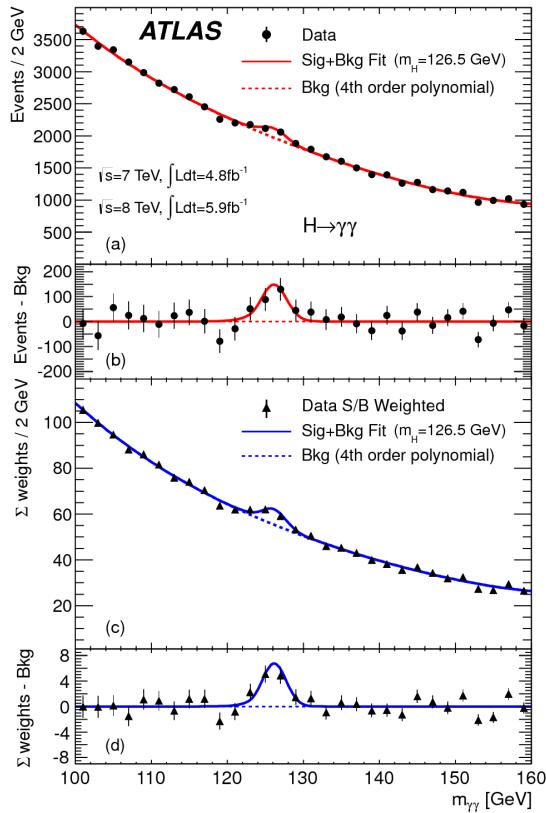

Figure 4.4: Diphoton mass spectrum in 7 and 8 TeV data. Panel a) shows the unweighted data distribution superimposed on the background fit, while panel c) shows the data where each event category is weighted by its signal to background ratio. Panels b) and d) show the respective distributions with background subtracted [1].

1634 4.5 $H \rightarrow ZZ \rightarrow 4\ell$ SEARCH

1635 The $H \rightarrow ZZ \rightarrow 4\ell$ analysis searches for a Standard Model Higgs boson decaying to two Z bosons, each
 1636 of which decays to a pair of same flavor, opposite charge isolated leptons. The ultimate discriminating
 1637 variable is $m_{4\ell}$, or the invariant mass of the four selected leptons. The ℓ denotes an e or μ as with the
 1638 $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis.

1639 Four distinct signal regions are constructed depending on the flavors of the final state, additionally sep-
 1640 arated by the flavor of the leading lepton pair. These are referred to as $4e$, $2e2\mu$, $2\mu2e$, 4μ .

1641 The main backgrounds in the $H \rightarrow ZZ \rightarrow 4\ell$ search are continuum ZZ^* production, $Z + \text{jets}$ pro-
 1642 duction, and $t\bar{t}$. The $m_{4\ell}$ distribution for background is estimated from simulation. The normalization
 1643 of the SM ZZ^* background is also taken from MC simulation, while the $Z + \text{jets}$ and $t\bar{t}$ normalizations are
 1644 taken from data-driven methods.

1645 **4.5.1 RESULTS**

1646 Figure 4.5 shows the $m_{4\ell}$ spectrum measured in the 7 and 8 TeV datasets. The total number of events
 1647 observed in the window between 120 and 130 GeV is 13, with 6 events in the 4μ channel, 2 events in
 1648 the $4e$ channel, and 5 events in the $2e2\mu/2\mu2e$. The best fit μ value in the combined 7 and 8 TeV data
 1649 occurs at 125 GeV and is measured to be 1.2 ± 0.6 . The observed significance at this mass is 3.6σ , with
 1650 an expected significance of 2.7σ .

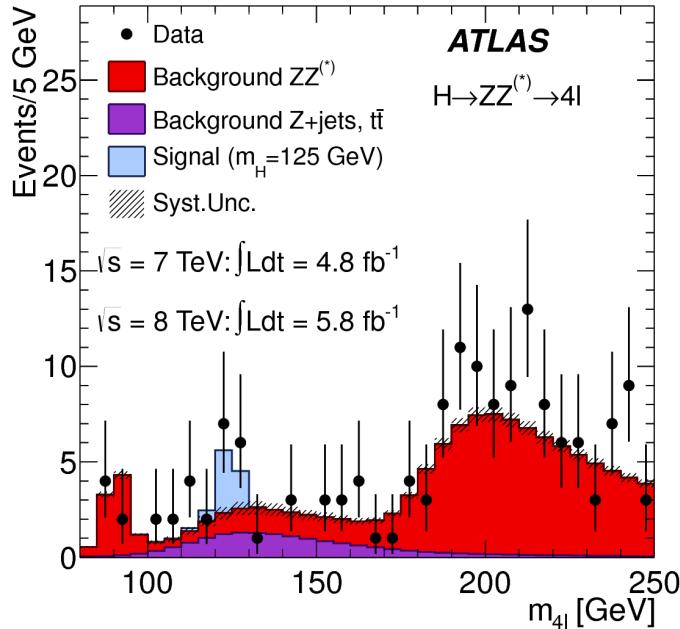

Figure 4.5: Four lepton invariant mass spectrum ($m_{4\ell}$) in 7 and 8 TeV data compared to background estimate. A 125 GeV SM Higgs signal is shown in blue [1].

1651 4.6 COMBINED RESULTS

1652 The statistical interpretation of the combined results is undertaken as described in section 3.6.2, with a hy-
1653 pothesis test based on a likelihood ratio parameterized by the Higgs signal strength μ . The null hypothesis
1654 corresponds to $\mu = 0$, while the SM Higgs corresponds to $\mu = 1$.

1655 Table 4.4 summarizes the properties of the individual channels as well as the significances of the excesses
1656 seen. The most significant observed local excess comes from the $\gamma\gamma$ channel. Figure 4.6 shows a com-
1657 parison of the observed local p_0 values as a function of hypothesized mass for the three different search
1658 channels. Both the ZZ^* and $\gamma\gamma$ channels have very peaked excesses, while the WW^* excess can be seen as
1659 very broad because the m_T distribution does not provide detailed information about the true Higgs mass.
1660 Figure 4.7 shows the combined exclusion limit, p_0 , and signal strength. The highest local excess comes at
1661 a value of 126.5 GeV and corresponds to a 6.0σ observed excess.

Channel	Fit var.	Observed Z_l	Expected Z_l	$\hat{\mu}$
$H \rightarrow ZZ^* \rightarrow 4\ell$	$m_{4\ell}$	3.6	2.7	1.2 ± 0.6
$H \rightarrow \gamma\gamma$	$m_{\gamma\gamma}$	4.5	2.5	1.8 ± 0.5
$H \rightarrow WW^* \rightarrow e\nu\mu\nu$	m_T	2.8	2.3	1.3 ± 0.5
Combined	-	6.0	4.9	1.4 ± 0.3

Table 4.4: Summary of the expected and observed significance and measured signal strengths in the combined 7
and 8 TeV datasets for the Higgs discovery analysis [1].

1662 Figure 4.8 shows a comparison of the measured signal strengths between the different Higgs search
1663 channels. All measured μ are consistent with unity within their uncertainty, and the combined μ mea-
1664 surement is 1.4 ± 0.3 .

1665 The likelihood can also be computed in a two-dimensional plane of m_H and μ , and this is shown in
1666 figure 4.9. The figure shows that while the $\gamma\gamma$ and ZZ^* channels have very good mass resolution, the
1667 excess in WW^* covers a broad mass range. The banana shape of the WW^* result is due to the fact that
1668 the excess in this channel can either be explained by increasing the signal strength or by changing the mass
1669 (and thus the cross section). The two parameters are correlated due to the lack of mass sensitivity in this
1670 channel.

1671 Because multiple Higgs mass points are searched for, the local significance must be corrected for a look-

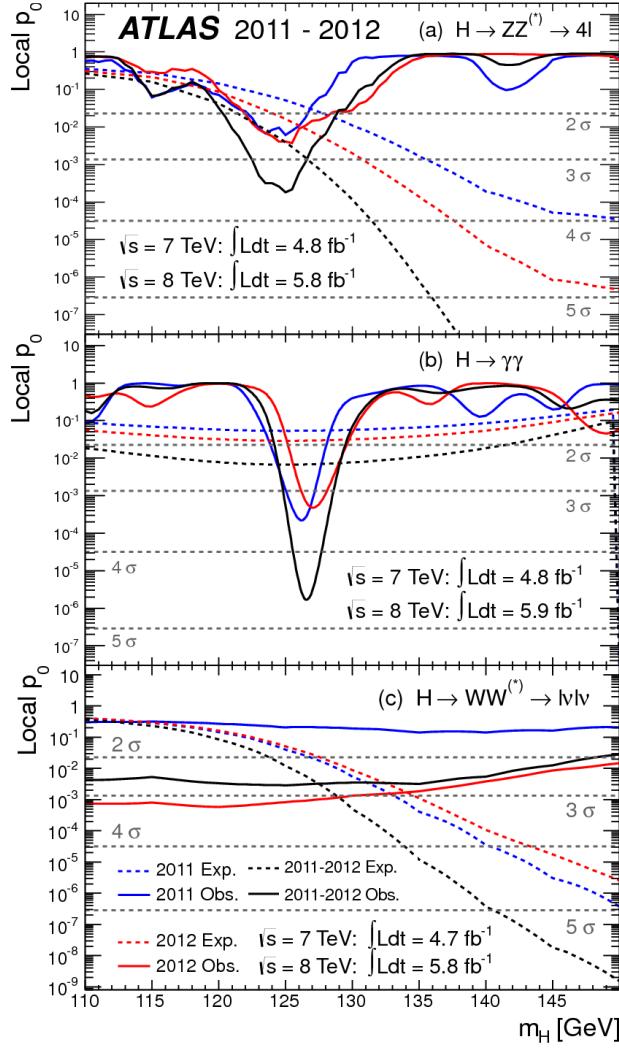

Figure 4.6: Local p_0 distribution as a function of hypothesized Higgs mass for the $H \rightarrow ZZ^* \rightarrow 4\ell$ (a), $H \rightarrow \gamma\gamma$ (b), and $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ (c) channels. Dashed curves show expected results, while solid curves show observed. Red curves are from 7 TeV data, blue curves from 8 TeV, and black curved combined [1].

1672 elsewhere effect to compute a true global significance. The global significance for finding a Higgs anywhere
 1673 in the mass range of 110 GeV to 600 GeV is 5.1σ . This increases slightly to 5.3σ if only mass range from
 1674 110 to 150 GeV.

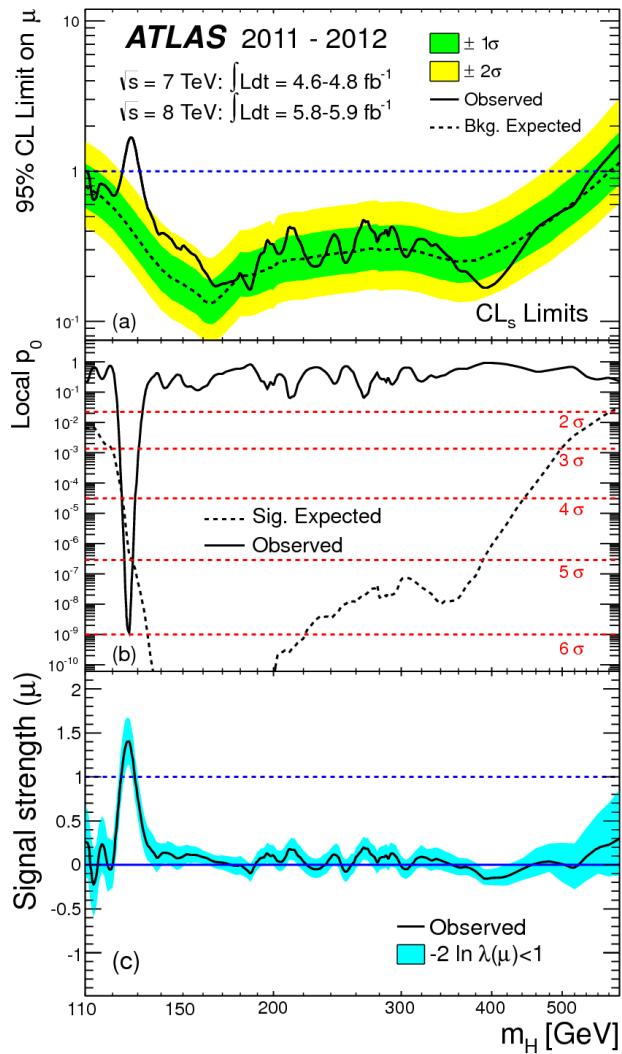

Figure 4.7: Combined 95% CL limits (a), local p_0 values (b), and signal strength measurement (c) as a function of Higgs mass [1].

1675 4.7 CONCLUSION

1676 A search for the production of a Standard Model Higgs boson was conducted in 4.8 fb^{-1} collected at
 1677 $\sqrt{s} = 7 \text{ TeV}$ and 5.8 fb^{-1} at $\sqrt{s} = 8 \text{ TeV}$. A new particle consistent with the Higgs boson was observed,
 1678 with a mass of 126.5 GeV and a global (local) significance of $5.1(6.0)\sigma$. This is the first discovery level
 1679 observation of a particle consistent with the Higgs.

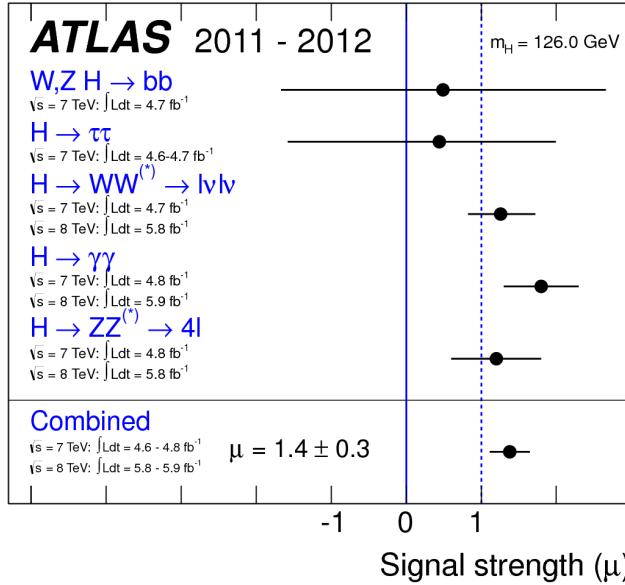

Figure 4.8: Comparison of measured signal strength μ for a 126 GeV Higgs in the 7 and 8 TeV datasets [1].

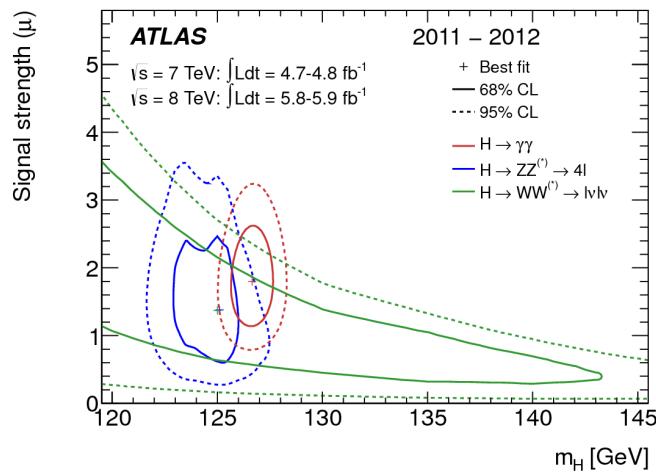

Figure 4.9: Two dimensional likelihood as a function of signal strength μ and Higgs mass m_H [1].

The imagination of nature is far, far greater than the imagination of man.

1680

1681 Evidence for Vector Boson Fusion production

1682

$$\text{of } H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$$

1683

5.1 INTRODUCTION

1684 After the discovery of the Higgs boson, the $H \rightarrow WW^*$ analysis had two main goals. The first goal was
1685 to increase the sensitivity of the analysis to fully confirm that the $H \rightarrow WW^*$ process did indeed exist.
1686 The second goal was to characterize the particle as much as possible, including searching for the lower
1687 cross-section production modes. This chapter presents a dedicated search for Vector Boson Fusion (VBF)
1688 production of a Higgs boson decaying via the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ mode. First, the data and Monte
1689 Carlo samples are detailed, along with trigger and physics object selections. Then, the details of the analysis
1690 are shown, including signal region definition, background estimation techniques, and systematic uncer-
1691 tainties. Finally, the results of the analysis are presented. As will be shown, this analysis is the first and

1692 most sensitive evidence for VBF production of the Higgs at the LHC.

1693 The VBF $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis defines two signal regions. The first is a more standard
1694 selection, referred to as “cut-based”, that applies requirements on VBF topology variables and uses m_T as
1695 the final discriminating variable. The second is a looser selection that uses an algorithm known as a Boosted
1696 Decision Tree (BDT). A BDT is a multivariate technique that uses an ensemble of decision trees to split the
1697 phase space of input variables into signal-like and background-like regions in order to provide separation
1698 power [79–81]. The output score of a BDT trained to distinguish the VBF Higgs signal from background
1699 processes is used as the final discriminating variable in the second signal region. While the BDT-based
1700 signal region is ultimately more sensitive, the cut-based result is an important component of the analysis.
1701 First, the cut-based analysis allows for confirming the modeling and validity of the variables used as input
1702 to the BDT. Second, because this is the first use of a multivariate technique in the $H \rightarrow WW^*$ analysis,
1703 the cut-based selection allows confirmation of the final BDT result with a more traditional analysis. The
1704 cut-based techniques are the focus of this chapter, but connections to the BDT result will be illustrated
1705 when appropriate.

1706 One important note is that because this analysis is dedicated to the measurement of the VBF pro-
1707 duction mode of the Higgs, events coming from gluon fusion production with the Higgs decaying via
1708 $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ are treated as background events. This will be seen throughout the background
1709 predictions shown below.

1710 **5.2 DATA AND SIMULATION SAMPLES**

1711 The results presented here are with 20.3 fb^{-1} taken at $\sqrt{s} = 8 \text{ TeV}$ and 4.5 fb^{-1} taken at $\sqrt{s} = 7 \text{ TeV}$.
1712 The details of the LHC and detector conditions during this period are given in Chapter 2. The trigger
1713 selection defining the dataset is discussed in section 5.2.1. The simulation samples used for signal and back-
1714 ground modeling are given in section 5.2.2.

1715 5.2.1 TRIGGERS

1716 The analysis uses a combination of single lepton and dilepton triggers to allow lowering of the p_T thresh-
1717 olds and increased signal acceptance. The p_T threshold on the leptons is a particularly important con-
1718 sideration for this signal. Because the W^* produced in the decay is off-shell, it tends to produce lower
1719 momentum leptons. Thus, being able to lower the p_T threshold while still maintaining a low background
1720 rate is critical. Figure 5.1 shows an example of the subleading lepton p_T for a VBF $H \rightarrow WW^*$ signal com-
1721 pared to the corresponding $t\bar{t}$ background. Note that the lepton p_T spectrum is considerably softer in the
1722 signal sample. The spectrum shown here is also similar in gluon fusion production of the Higgs as well.

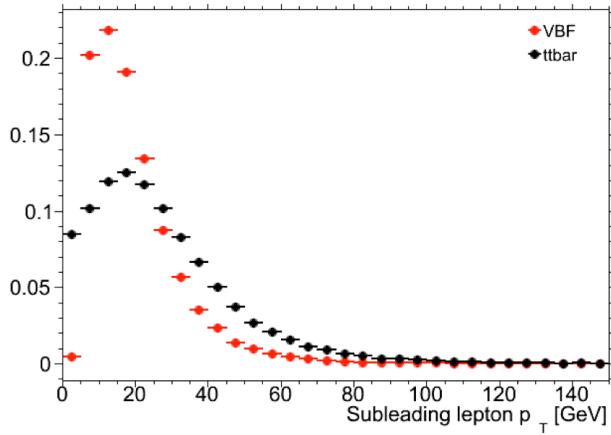

Figure 5.1: A comparison of the subleading lepton p_T spectrum between VBF $H \rightarrow WW^*$ production and $t\bar{t}$ background.

1723 As discussed in Chapter 2, there are multiple levels in the ATLAS trigger system, and there are different
1724 p_T thresholds imposed for the leptons at each level. Additionally, some triggers have a loose selection on
1725 the isolation of the lepton (looser than that applied offline in the analysis object selection). Table 5.1 shows
1726 the p_T thresholds used for single lepton triggers, while table 5.2 shows the p_T thresholds coming from
1727 di-lepton triggers. The single lepton trigger efficiency for muons that pass the analysis object selection is
1728 70% for muons in the barrel region ($|\eta| < 1.05$) and 90% in the endcap region. The electron trigger
1729 efficiency increases with electron p_T but the average is approximately 90%. These efficiencies are measured
1730 by combined performance and trigger signature groups [82, 83].

	Level-1 threshold	High-level threshold
Electron	18	$24i$
	30	60
Muon	15	$24i$
		36

Table 5.1: Single lepton triggers used for electrons and muons in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis. A logical “or” of the triggers listed for each lepton type is taken. Units are in GeV, and the i denotes an isolation requirement in the trigger.

	Level-1 threshold	High-level threshold
ee	10 and 10	12 and 12
$\mu\mu$	15	18 and 8
$e\mu$	10 and 6	12 and 8

Table 5.2: Di-lepton triggers used for different flavor combinations in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis. The two thresholds listed refer to leading and sub-leading leptons, respectively. The di-muon trigger only requires a single lepton at level-1.

1731 The combination of all listed triggers gives good efficiency for signal events. This efficiency is summa-
 1732 rized in table 5.3. The relative improvement in efficiency by adding the dilepton triggers is also shown
 1733 in the same table. The largest gain comes in the $\mu\mu$ channel. Overall the trigger selection shows a good
 1734 efficiency for $H \rightarrow WW^*$ signal events.

Channel	Trigger efficiency	Gain from 2ℓ trigger
ee	97%	9.1%
$\mu\mu$	89%	18.5%
$e\mu$	95%	8.3%
μe	81%	8.2%

Table 5.3: Trigger efficiency for signal events and relative gain of adding a dilepton trigger on top of the single lepton trigger selection. The first lepton is the leading, while the second is the sub-leading. Efficiencies shown here are for the ggF signal in the $n_j = 0$ category but are comparable for the VBF signal.

1735 5.2.2 MONTE CARLO SAMPLES

1736 In both the gluon fusion and vector boson fusion focused analyses, modeling of signal and background
 1737 processes in the signal region is an important consideration for the final interpretation of the analysis.
 1738 Therefore, careful consideration must be paid to which Monte Carlo (MC) generators are used for specific

1739 processes. With the exception of the $W + \text{jet}$ and multijet backgrounds, the m_T shape used as the final
1740 discriminant is taken from simulation¹.

1741 Table 5.4 shows the MC generators used for the signal and background processes, as well as the cross
1742 sections of each process. In order to include corrections up to next-to-leading order (NLO) in the QCD
1743 coupling constant α_s , the `POWHEG` [84] generator is often used. In some cases, only leading order gener-
1744 ators like `ACERMC` [85] and `GG2VV` [86] are available for the process in question. If the process requires
1745 good modeling for very high parton multiplicities, the `SHERPA` [87] and `ALPGEN` [88] generators are used
1746 to provide merged calculations for five or fewer additional partons. These matrix element level calculations
1747 must then be additionally matched to models of the underlying event, hadronization, and parton shower.
1748 There are four generators used for this purpose: `SHERPA`, `PYTHIA 6` [89], `PYTHIA 8` [90], or `HERWIG`
1749 [91] + `JIMMY` [92]. The simulation additionally requires an input parton distribution function (PDF).
1750 The `CT10` [93] PDFs are used for `SHERPA` and `POWHEG` simulated samples, while `CTEQ6L1` [94] is used
1751 for `ALPGEN + HERWIG` and `ACERMC` simulations. The Drell-Yan samples are reweighted to the `MRST` [95]
1752 PDFs, as these are found to give the best agreement between data and simulation. The branching ratio
1753 for Higgs to WW^* and ZZ^* is computed with `PROPHECY4f` [96], while the width of all other decays is
1754 computed with `HDECAY`[97].

1755 Once the basic hard scattering process is simulated, it must be passed through a detector simulation and
1756 additional pile-up events must be overlaid. The pile-up events are modeled with `PYTHIA 8`, and the ATLAS
1757 detector is simulated with `GEANT4` [98]. Because of the unique phase space of the $H \rightarrow WW^*$ analysis,
1758 events are sometimes filtered at generator level to allow for more efficient generation of relevant events.
1759 The efficiency of the trigger in MC simulation does not always match the measured efficiency in data, so
1760 trigger scale factors are applied to correct the MC efficiency to the data. The details of these corrections are
1761 given in reference [82] for muons and reference [83] for electrons.

¹Many backgrounds are normalized from data, as described in section 5.5.

Table 5.4: Monte Carlo samples used to model the signal and background processes [74]. The table lists the cross section for each process, taking into account the branching ratio for the process producing two leptons.

1762 5.3 OBJECT SELECTION

1763 In order to define the signal region, the analysis must first select the reconstructed physics objects to be
1764 considered. The details of the object reconstruction algorithms were discussed in Chapter 2, while this

1765 section gives specific selection requirements used in the $H \rightarrow WW^*$ analysis. The first step in this process
1766 is to select a primary vertex candidates. The event's primary vertex is chosen to be the vertex with the largest
1767 sum of p_T^2 for its associated tracks. It is required to have at least three tracks with $p_T > 450$ MeV. Many
1768 of the object selection cuts are then made relative to this chosen primary vertex.

1769 **5.3.1 MUONS**

1770 The analysis uses combined muon candidates, where a track in the Inner Detector has been matched to a
1771 standalone track in the Muon Spectrometer. The track parameters are combined statistically in the muon
1772 reconstruction algorithm [64]. The muons are required to be within $|\eta| < 2.5$ and have a $p_T > 10$ GeV.
1773 To reduce backgrounds coming from mis-reconstructed leptons, there are requirements on the impact
1774 parameter of the muon relative to the primary vertex. The transverse impact parameter d_0 is required to
1775 be small relative to its estimated uncertainty, the exact cut value being $d_0/\sigma_{d_0} < 3$. The longitudinal
1776 impact parameter z_0 must satisfy $|z_0 \sin \theta| < 1$ mm.

1777 As discussed previously, the muons must also be isolated. There are two types of lepton isolations
1778 that are calculated: track-based and calorimeter-based. For muons, the track-based isolation is defined
1779 using the scalar sum $\sum p_T$ for tracks with $p_T > 1$ GeV (excluding the muon track) within a cone of
1780 $\Delta R = 0.3$ (0.4) around the track for muons with $p_T > 15$ GeV ($10 < p_T < 15$ GeV). The final
1781 isolation requirement is made by requiring that this scalar sum be no more than a certain fraction of the
1782 muon p_T . This requirement varies with muon p_T and the exact requirements are defined in table 5.5.

1783 The calorimeter-based muon isolation is defined using the $\sum E_T$ calculated from calorimeter cells with
1784 the same cone size as the track-based isolation but excluding cells within $\Delta R < 0.05$ around the muon.
1785 This isolation is also defined as a requirement on the ratio of the sum to the muon p_T and varies with
1786 muon p_T . The requirement values as a function of p_T are also given in table 5.5.

1787 The isolation requirements loosen as a function of p_T to allow for larger signal acceptance. At low p_T ,
1788 the isolation is tightened to reduce the $W + \text{jets}$ background which arises from a misidentified lepton.

p_T range (GeV)	Calorimeter isolation	Track isolation
10 – 15	0.06	0.06
15 – 20	0.12	0.08
20 – 25	0.18	0.12
> 25	0.30	0.12

Table 5.5: p_T dependent isolation requirements for muons. Muons are required to have their calorimeter based or track based cone sums be less than this fraction of their p_T .

1789 5.3.2 ELECTRONS

1790 Electrons are identified and reconstructed using the methods previously described in chapter 2. The elec-
 1791 trons are required to have $|\eta| < 2.47$, and candidates in the transition region between the barrel and
 1792 endcap ($1.37 < |\eta| < 1.52$) are excluded. As the muons, the electrons are required to have transverse
 1793 impact parameter significance < 3 , while in the longitudinal direction they must have $|z_0 \sin \theta| < 0.4$
 1794 mm. Some electron requirements also vary with electron E_T , and these requirements are summarized in
 1795 table 5.6.

1796 The isolation for electrons is defined similarly to the muons but with unique requirements on the ob-
 1797 jects included. The track-based isolation is constructed using tracks with $p_T > 400$ MeV with cone sizes
 1798 as defined for the muons. The calorimeter-based isolation also uses the same cone size as the muon, but
 1799 here the cells within a 0.125×0.175 area in $\eta \times \phi$ around the electron cluster's barycenter are excluded.
 1800 The other difference with respect to muons is that the denominator of the isolation ratio is the electron
 1801 E_T rather than p_T . The isolation cuts very with electron E_T and are defined in table 5.6. The electron is
 1802 also required to not be consistent with a vertex coming from a photon conversion.

p_T range (GeV)	Quality cut	Calorimeter isolation	Track isolation
10 – 15	Very tight LH	0.20	0.06
15 – 20	Very tight LH	0.24	0.08
20 – 25	Very tight LH	0.28	0.10
> 25	Medium	0.28	0.10

Table 5.6: p_T dependent requirements for electrons. Electrons are required to have their calorimeter based or track based cone sums be less than this fraction of their E_T .

1803 5.3.3 JETS

1804 Jets are clustered with the anti- k_T reconstruction algorithm using a radius parameter of $R = 0.4$. They
1805 are required to have a jet vertex fraction (JVF) of at least 50%, meaning that half of the tracks associated with
1806 the jet originated from the primary vertex. Jets with no tracks associated (i.e. those outside the acceptance
1807 of the ID) do not have this requirement applied. Jets are required to have $p_T > 25$ GeV if they are within
1808 the tracking acceptance ($|\eta| < 2.4$). Jets with $2.4 < |\eta| < 4.5$ are required to have $p_T > 30$ GeV. This
1809 tighter requirement reduces jets from pileup in the region where JVF requirements cannot be applied. The
1810 two highest p_T jets in the event are referred to as the “VBF” jets and used to compute variables used in the
1811 analysis selection.

1812 Identification of b -jets is done using the MV1 algorithm and is limited to the acceptance of the ID ($|\eta| <$
1813 2.5) [70]. The operating point of MV1 used is 85% efficient for identifying true b -jets. This operating
1814 point has a 10.3% probability of mis-tagging a light quark jet as a b -jet. The analysis vetoes events that
1815 contain b -tagged jets with $p_T > 20$ GeV.

1816 5.3.4 OVERLAP REMOVAL

1817 There are some cases where reconstructed objects will overlap and one will have to be chosen (for example,
1818 an electron and a jet in the calorimeter). First, the case of lepton overlap is dealt with. If an electron
1819 candidate extends into the muon spectrometer, it is removed. If a muon and electron are within $\Delta R < 0.1$
1820 of each other, the electron is removed and the muon is kept. If two electron candidates overlap within the
1821 same radius, then the higher E_T electron is kept. Next, the overlap between leptons and jets is considered.
1822 If an electron and jet are within $\Delta R < 0.3$ of one another, the electron is kept and the jet is removed.
1823 However, if a muon and jet overlap within $\Delta R < 0.3$, the jet is kept (as it is likely that the muon is the
1824 result of a semileptonic decay inside the jet). Once the overlap removal is complete, the final set of objects
1825 used in the analysis is defined.

1826 **5.4 ANALYSIS SELECTION**

1827 This section discusses the variables used to distinguish VBF production of the Higgs in the $H \rightarrow WW^* \rightarrow$
1828 $\ell\nu\ell\nu$ final state. First, pre-selection requirements are presented. Then, the definitions of analysis variables
1829 and the cut-based signal region are shown. Finally, the BDT signal region is defined and the commonalities
1830 between the two signal regions are discussed.

1831 **5.4.1 PRE-SELECTION**

1832 Both the cut-based and BDT analyses have a common pre-selection that is applied before the signal region
1833 requirements. The requirements on leptons are common to all n_j bins. The analysis requires two oppo-
1834 sitely charged leptons, with the leading lepton required to have $p_T > 22$ GeV while the subleading lepton
1835 must have $p_T > 10$ GeV. Next, to remove low mass Z/γ^* events, a requirement on the dilepton mass
1836 $m_{\ell\ell} > 10$ (12) GeV is applied in the different (same) flavor channel. In the same flavor channels, there is
1837 an additional veto placed on the region around the Z peak, requiring that $|m_{\ell\ell} - m_Z| > 15$ GeV.

1838 There are also requirements on the amount of missing transverse momentum in the event. These
1839 are only applied in the same flavor channels, where $Z/\gamma^* + \text{jets}$ production is one of the dominant back-
1840 grounds. The BDT analysis requires $p_T^{\text{miss}} > 40$ GeV and $E_T^{\text{miss}} > 45$ GeV. The cut-based analysis
1841 must select more tightly on these variables to have maximal sensitivity and thus requires $p_T^{\text{miss}} > 50$ GeV
1842 and $E_T^{\text{miss}} > 55$ GeV.

1843 Finally, because this analysis is focused on VBF Higgs production, a requirement on the jet multiplicity
1844 is placed, with $n_j \geq 2$. Additionally, the analysis requires that there are no jets identified as b-quarks in
1845 the event, or $n_b = 0$.

1846 **5.4.2 ANALYSIS VARIABLE DEFINITIONS AND CUT-BASED SELECTION**

1847 The cut-based selection places sequential requirements on variables reconstructed from the VBF jets in
1848 order to increase the signal to background ratio. This section defines the variables that are used in the
1849 cut-based selection and details the requirements that are placed on these variables.

1850 GENERAL BACKGROUND REDUCTION

1851 Top pair production is the primary background in the $n_j \geq 2$ bin. Even though $n_b = 0$ is required, an
1852 additional variable is constructed to further suppress the top background. There is often additional QCD
1853 radiation that accompanies the $t\bar{t}$ system when it is produced. Therefore, a variable which tests for the
1854 presence of this additional radiation, p_T^{sum} , is constructed. It is defined in equation 5.1.

$$p_T^{\text{sum}} = p_T^{\ell\ell} + p_T^{\text{miss}} + \sum p_T^j \quad (5.1)$$

1855 After pre-selection, the cut-based analysis requires the event to have $p_T^{\text{sum}} < 15$ GeV to further suppress
1856 $t\bar{t}$ production.

1857 In the different flavor channels, a requirement is made to reduce the contamination from $Z \rightarrow \tau\tau$
1858 decays. The di- τ invariant mass, $m_{\tau\tau}$, is constructed by assuming that the neutrinos from the τ decays
1859 were collinear with the leptons [77]. The analysis requires that this mass satisfy $m_{\tau\tau} < m_Z - 25$ GeV so
1860 that it is not consistent with the mass of the Z boson.

1861 VBF TOPOLOGICAL CUTS

1862 The characteristic feature of VBF production of the Higgs is the presence of two additional forward jets
1863 coming from the incoming partons which radiate the vector bosons that make the Higgs. These jets are
1864 forward because the outgoing partons still carry the longitudinal momentum of the incoming partons.
1865 Figure 5.2 shows the distribution of the η for the leading jet in a VBF event compared to a background top
1866 pair production event. As can be seen, the VBF jets tend to be more forward in η , while the $t\bar{t}$ jets are more
1867 central. Because the cross section for VBF production is an order of magnitude smaller than gluon fusion
1868 production, these forward jets must be used in order to reduce background and achieve a good signal to
1869 background ratio. The dedicated VBF search selection requirements are constructed to maximally exploit
1870 the features of the unique VBF topology.

1871 Requirements on the VBF jets are collectively referred to as the “VBF topological cuts”. First, a require-
1872 ment on the dijet invariant mass of the VBF jets, m_{jj} , is placed, requiring $m_{jj} > 600$ GeV. Next, the

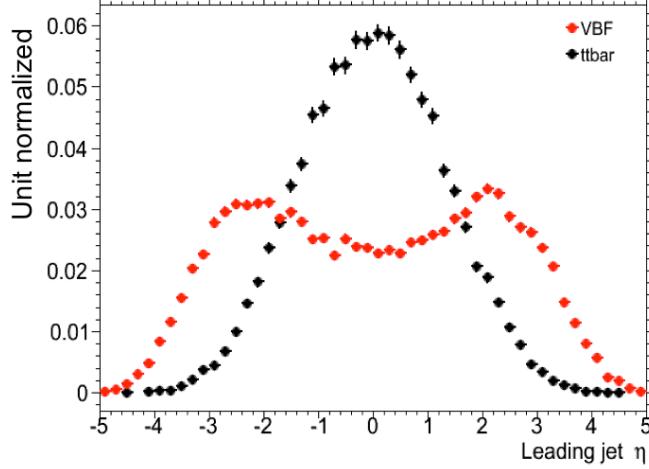

Figure 5.2: Leading jet η in VBF $H \rightarrow WW^*$ (red) and $t\bar{t}$ (black)

event is required to have a large gap in rapidity between the two VBF jets, or $\Delta y_{jj} > 3.6$. Both of these are tight requirements on the presence of two forward, high p_T jets moving in opposite directions in the longitudinal plane.

Beyond requiring the presence of the two forward VBF jets, the analysis also vetoes on the presence of any additional jets that fall between the two VBF jets. This requirement is referred to as the central jet veto, or CJV. Events are vetoed if they have a third jet with $p_T > 20$ GeV whose rapidity is between the region defined by the two VBF jets. This requirement can be expressed in terms of a variable called the jet centrality, defined in equation 5.2.

$$C_{j3} = \left| \eta_{j3} - \frac{\eta_{j1} + \eta_{j2}}{2} \right| / \frac{|\eta_{j1} - \eta_{j2}|}{2}, \quad (5.2)$$

Here, η_{j1} and η_{j2} are the pseudorapidities of the leading and subleading jets, respectively, while η_{j3} is the pseudorapidity of the extra jet in the event (if one exists). Intuitively, C_{j3} is zero when η_{j3} is directly centered between the two jets and unity when η_{j3} is aligned with either of the VBF jets. Thus, the CJV can be expressed as a requirement that $C_{j3} > 1$.

The decay products of the Higgs tend to be central as well. Thus, the analysis also requires that both

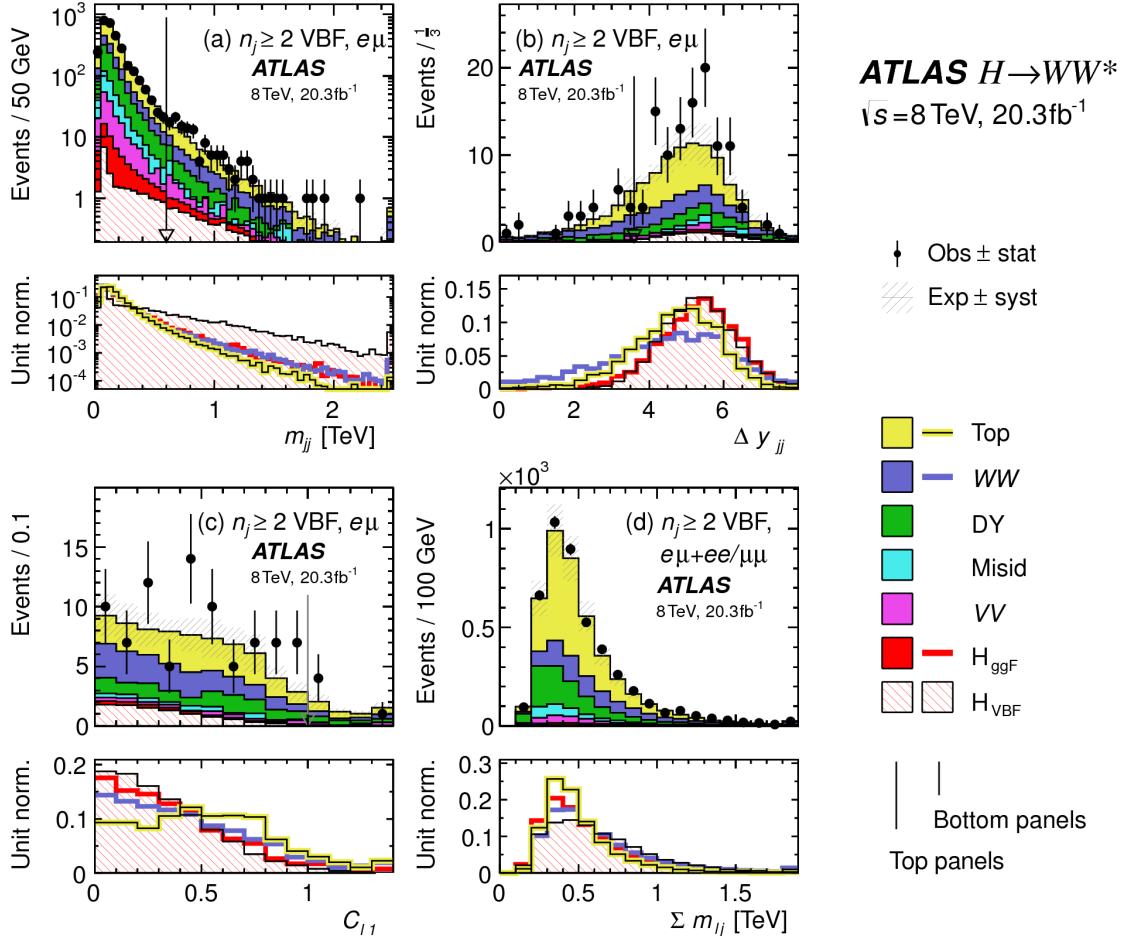

Figure 5.3: Distributions of (a) m_{jj} , (b) Δy_{jj} , (c) $C_{\ell 1}$, and (d) $\Sigma m_{\ell j}$, for the cut-based VBF analysis. The top panels compare simulation and data, while the bottom panels show normalized distributions for all background processes and signal for shape comparisons [74].

leptons in the analysis fall within the rapidity gap defined by the jets. This cut is referred to as the outside lepton veto, or OLV. Stated another way, leptons are required to have a centrality (defined analogously to that of the third jet in equation 5.2) within the jet rapidity gap, or $C_{\ell} < 1$ for both leptons.

Figure 5.3a-c shows the m_{jj} , Δy_{jj} , and $C_{\ell 1}$ variables at the stage where all previous requirements in the sequence have been made. The agreement between data and Monte Carlo is good, and the bottom panels show their power in discriminating the VBF signal from the background processes.

The final signal region is also split into two bins of m_{jj} , with the first bin corresponding to $600 \text{ GeV} < m_{jj} < 1 \text{ TeV}$ and the second bin corresponding to $m_{jj} > 1 \text{ TeV}$. The first bin has more events but also

1894 a larger contribution from background, while the second bin has a lower expected number of events but a
1895 1:1 signal to background ratio.

1896 HIGGS TOPOLOGICAL CUTS

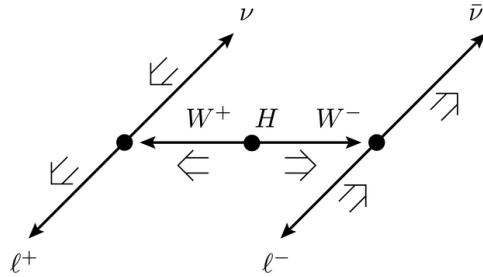

Figure 5.4: A cartoon of the WW final state. Momenta are represented with thin arrows, spins with thick arrows [74].

1897 The final state leptons will exhibit unique correlations due to the fact that they arise from the decay of
1898 a spin zero resonance. These characteristics are present in $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ decays regardless of the
1899 production mode being studies. In particular, the spins of the final state leptons and neutrinos must all
1900 cancel, as shown in figure 5.4. Because the neutrino has a left handed chirality and the anti-neutrino has a
1901 right handed chirality (in the massless neutrino approximation), the spin and momentum of the particles
1902 will be anti-aligned and aligned, respectively. In the transverse plane, the momenta of all four final state
1903 objects must cancel as well. With the constraint of having both the momenta and the spin alignments
1904 cancel, the final state kinematics strongly prefer having a small angle between the leptons in the transverse
1905 plane (low $\Delta\phi_{\ell\ell}$). This angular correlation will also lead to low values of the di-lepton invariant mass $m_{\ell\ell}$.
1906 These unique signal final state kinematic correlations are exploited to define the ultimate signal region.

1907 Two requirements on dilepton kinematics are made that are common with lower multiplicity jet bins
1908 as well. The angle between leptons in the transverse plane, $\Delta\phi_{\ell\ell}$, is required to be less than 1.8 radians.
1909 Additionally, the dilepton invariant mass, $m_{\ell\ell}$, is required to be less than 50 GeV.

1910 The cut-based analysis uses m_T as the final discriminating variable as in the ggF focused analysis. The
1911 optimal number of bins in m_T was found to be three bins, with the bin boundaries at 80 and 130 GeV.

1912 Table 5.7 shows a summary of the data and estimated signal and background yields from simulation
 1913 as each requirement described above is made. The table shows how the overall signal to background ra-
 1914 tio grows through the various selection requirements. Table 5.8 shows the background composition after
 1915 each selection requirement, illustrating which backgrounds are reduced most by certain requirements. Fig-
 1916 ure 5.5 shows an ATLAS event display of a candidate event in the final signal region.

Selection	Summary					
	$N_{\text{obs}}/N_{\text{bkg}}$	N_{obs}	N_{bkg}	N_{signal}

1917 5.4.3 BDT-BASED SELECTION

1918 The boosted decision tree based analysis uses many of the variables defined in the cut-based selection as
 1919 inputs to the BDT. The output BDT score (O_{BDT}) is used as the final discriminant rather than m_T ².
 1920 The BDT is trained with the VBF $H \rightarrow WW^*$ simulation as the signal samples and all other processes as
 1921 background, including ggF $H \rightarrow WW^*$ production. While the BDT based analysis is ultimately treated
 1922 as a separate result, it has significant overlap with the cut-based selection.

²For the final discriminant analysis, the O_{BDT} distribution is divided into four bins, with boundaries at $[-1, -0.48, -0.3, 0.78, 1]$.

	Composition of N_{bkg}

1923 PRE-TRAINING SELECTION AND BDT INPUTS

1924 Before training, the common pre-selection cuts described in section 5.4.1 are applied. Additionally, the
1925 central jet veto and outside lepton veto described in section 5.4.2 are applied. The BDT has eight input
1926 variables, six of which are also variables that are used in the cut-based analysis. The six shared variables
1927 are p_T^{sum} , m_{jj} , Δy_{jj} , $m_{\ell\ell}$, $\Delta\phi_{\ell\ell}$, and m_T . The seventh variable input in the BDT is a combination of
1928 the variables used to define the OLV in the cut-based analysis. The BDT uses as input the sum of lepton
1929 centralities, or $\sum C_\ell = C_{\ell 1} + C_{\ell 2}$. The final BDT input variable, $\Sigma m_{\ell j}$, is constructed to account for
1930 the correlations between the jets and leptons in the event. It is the sum of the invariant masses of all four
1931 possible lepton-jet combinations.

1932 Figure 5.3d shows the agreement between data and simulation for the $\Sigma m_{\ell j}$ variable, as well as showing
1933 its discriminating power. Figure 5.6 shows the distributions of the Higgs topological variables that are
1934 shared between the cut-based and BDT analyses. Figure 5.7 shows the distributions of the VBF topological
1935 variables shared between the cut-based and BDT analyses. In both cases, the VBF yield has been scaled by
1936 a factor of 50 to better show the shape difference compared to the backgrounds.

1937 5.5 BACKGROUND ESTIMATION

1938 This section describes the procedures used to estimate backgrounds for the VBF analysis in both the cut-
1939 based and BDT analyses.

1940 5.5.1 GENERAL STRATEGY

1941 Most of the backgrounds in both the gluon fusion and VBF Higgs analyses have shapes estimated from
1942 Monte Carlo simulation but normalizations derived from control regions in data. In essence, a normaliza-
1943 tion factor (denoted with β or abbreviated as NF) is derived by scaling the MC yield in the control region
1944 to the corresponding yield in data. Once this factor is derived, it can be used to scale the MC estimate of
1945 the background in the signal region. This is illustrated in equation 5.3.

$$B_{\text{SR}}^{\text{est}} = B_{\text{SR}} \times \frac{N_{\text{CR}}}{B_{\text{CR}}} \equiv B_{\text{SR}} \times \beta \quad (5.3)$$

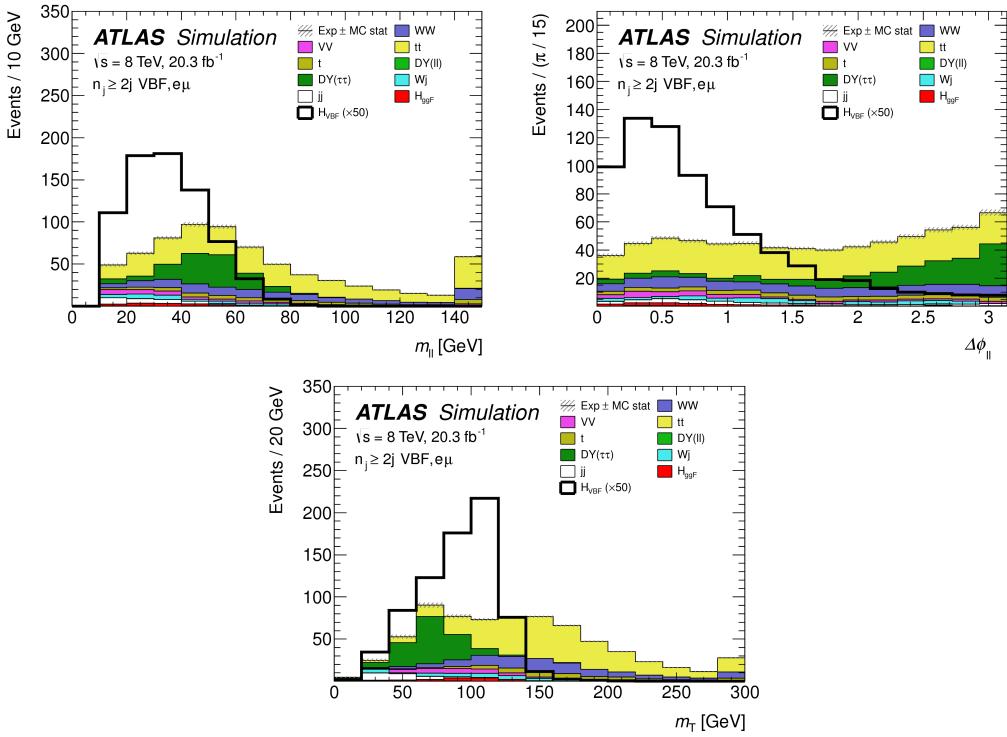

Figure 5.6: Higgs topology variables - $m_{\ell\ell}$ (top left), $\Delta\phi_{\ell\ell}$ (top right), and m_T (bottom) - used in the selection requirements of the cut-based signal region and as inputs to the BDT result. These are plotted after all of the BDT pre-training selection cuts [74]. The VBF Higgs signal cross section is multiplied by a factor of 50 to allow for shape comparisons.

1946 Here, B is the MC yield prediction in the denoted region, while N is the observed number of events in
 1947 data in the denoted region.

1948 There is an alternative way of writing the same equation in terms of an extrapolation factor α rather
 1949 than a normalization factor β . The overall calculation is exactly the same. However, when phrased in
 1950 this way, it shows how the uncertainty on the background estimation can be reduced. This is shown in
 1951 equation 5.4.

$$B_{\text{SR}}^{\text{est}} = N_{\text{CR}} \times \frac{B_{\text{SR}}}{B_{\text{CR}}} \equiv N_{\text{CR}} \times \alpha \quad (5.4)$$

1952 Phrased this way, the equation shows that with enough events in the control region, a large theoretical
 1953 uncertainty on the overall background yield in the signal region can be replaced by a small statistical un-
 1954 certainty coming from the number of data events in the CR and a smaller theoretical uncertainty on the
 1955 extrapolation from the control region to the signal region.

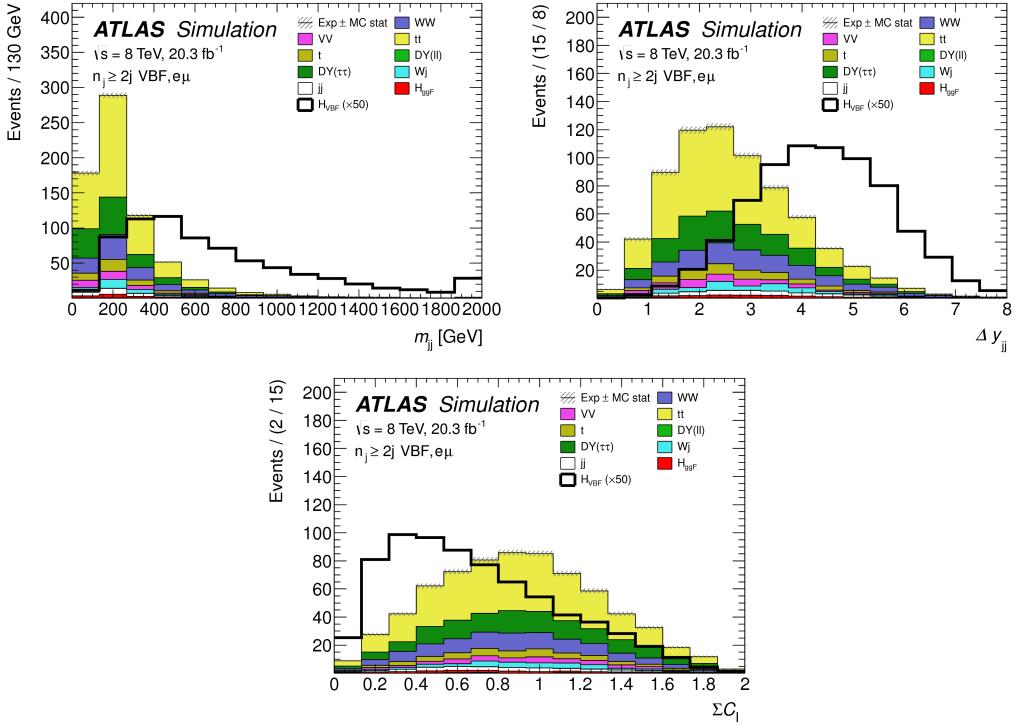

Figure 5.7: VBF topology variables - m_{jj} (top left), Δy_{jj} (top right), $\sum C_\ell$ (bottom) - used in the selection requirements of the cut-based signal region and as inputs to the BDT result. These are plotted after all of the BDT pre-training selection cuts [74]. The VBF Higgs signal cross section is multiplied by a factor of 50 to allow for shape comparisons.

1956 5.5.2 TOP BACKGROUND

1957 The normalization factor β_t for the top background in the VBF analysis is derived in a region required to
 1958 have one b -tagged jet, or $n_b = 1$. In the cut-based analysis, normalization factors are computed after every
 1959 selection requirement by making the same requirements in the CR. These NF are then applied to the $t\bar{t}$ and
 1960 single top event yields in the SR. In the BDT analysis, a single normalization factor is computed for each
 1961 bin of O_{BDT} after applying the BDT pre-training cuts described previously. The computed normaliza-
 1962 tion factors are derived with all flavor combinations combined in order to decrease statistical uncertainty.
 1963 Additionally, in the BDT analysis, BDT bins 2 and 3 are merged for the same reason.

1964 Table 5.9 shows the evolution of the β_t through the cut-based selection. Table 5.10 shows the value of the
 1965 β_t in each bin of O_{BDT} . The computed factors are almost all relatively consistent with unity, except for bin
 1966 1 of O_{BDT} which requires a larger correction. The normalization factors in bins 2 and 3 of O_{BDT} are also

¹⁹⁶⁷ consistent with those derived in the cut-based signal region, increasing confidence in the BDT estimation.

Figure 5.8 shows the m_{jj} and O_{BDT} distributions in the top control region. Overall the modeling looks

Cut	β_t
$p_T^{\text{sum}} < 15 \text{ GeV}$	1.03 ± 0.01
$m_{\tau\tau} < m_Z - 25$	1.05 ± 0.01
$m_{jj} > 600 \text{ GeV}$	0.96 ± 0.06
$\Delta y_{jj} > 3.6$	1.02 ± 0.08
CJV	1.13 ± 0.16
OLV	1.01 ± 0.19
$m_{jj} < 1 \text{ TeV}$	0.94 ± 0.19
$m_{jj} > 1 \text{ TeV}$	1.48 ± 0.66

¹⁹⁶⁸

¹⁹⁶⁹ consistent with the data. While these normalization factors can be computed and applied to the expected
¹⁹⁷⁰ background yields listed in tables like table 5.8, the final normalization of the top background is profiled
¹⁹⁷¹ (meaning there is a dedicated Poisson constraint) and allowed to float in the final statistical fit.

¹⁹⁷² 5.5.3 $Z/\gamma^* \rightarrow \tau\tau$ BACKGROUND

¹⁹⁷³ In the different flavor channels, the $Z/\gamma^* \rightarrow \tau\tau$ background is an important one. Di-tau production can
¹⁹⁷⁴ produce an $e\mu$ final state if each τ lepton decays to a different flavor lepton.

¹⁹⁷⁵ In the BDT analysis, a single normalization factor for the background is derived. A control region
¹⁹⁷⁶ is defined using the pre-training selection cuts, except requiring that $|m_{\tau\tau} - m_Z| < 25 \text{ GeV}$ so that
¹⁹⁷⁷ the region is enriched in $Z/\gamma^* \rightarrow \tau\tau$ background. Additional requirements of $m_{\ell\ell} < 80(75) \text{ GeV}$
¹⁹⁷⁸ in the different (same) flavor channel, as well as $O_{\text{BDT}} > -0.48$ are applied to increase the purity of the

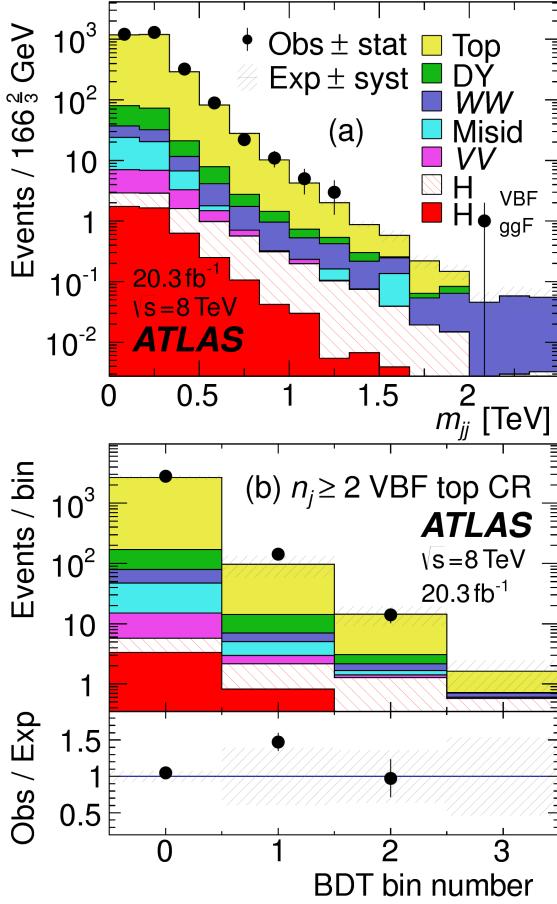

Figure 5.8: Distributions of m_{jj} (a) and O_{BDT} (b) in the VBF $n_b = 1$ top CR [74].

region. The final $\beta_{Z/\gamma^* \rightarrow \tau\tau}$ is calculated to be 0.9 ± 0.3 (statistical uncertainty only). Because of the small contribution of this background in the BDT analysis and the large statistical uncertainty, no additional systematics are calculated. The final SR estimate is scaled by this β and not allowed to float in the fit.

The cut-based corrections are a bit more involved because they need to be applied selection by selection, as well as in the final signal region for the fit. The control region is defined including all SR requirements up to the $Z/\gamma^* \rightarrow \tau\tau$ veto, which is instead turned into a Z mass peak requirement as for the BDT region. The $m_{\ell\ell}$ cut from the BDT region is included as well. The cut-based approach aims to correct the normalization of the $Z/\gamma^* \rightarrow \tau\tau$ background in two ways. First, an overall normalization factor is computed from the control region. However, the VBF topological cuts are not included in this region, and applying them as is done in the top CR is not feasible due to limited statistics. So, instead, correction

1989 factors (CF) to the cut efficiencies of the VBF cuts are derived in a same flavor $Z \rightarrow \ell\ell$ control region,
 1990 which has significantly more statistics. The CF is simply the ratio of the cut efficiencies in data and MC
 1991 derived in this region. In the end, the overall background estimate is given by equation 5.5.

$$N_{Z/\gamma^* \rightarrow \tau\tau}^{\text{est}} = B_{Z/\gamma^* \rightarrow \tau\tau}^{\text{SR}} \times \beta_{\tau\tau} \times \frac{\epsilon_{\text{VBF cuts}}^{\text{data}}}{\epsilon_{\text{VBF cuts}}^{\text{MC}}} \quad (5.5)$$

1992 The hypothesis is that while the normalization correction must be derived in a dedicated region, the effi-
 1993 ciency of the VBF topology requirements should not be sensitive to the type of Z/γ^* process and thus the
 1994 higher number of events can be exploited to derive the CF. Figure 5.9 shows a shape comparison for the
 1995 m_{jj} variable in $Z \rightarrow \tau\tau$ events in the signal region and $Z \rightarrow \ell\ell$ events in the control region. The figure
 1996 shows that the shapes are indeed comparable and thus any CF derived in the same flavor control region
 1997 can reliably be applied in the signal region.

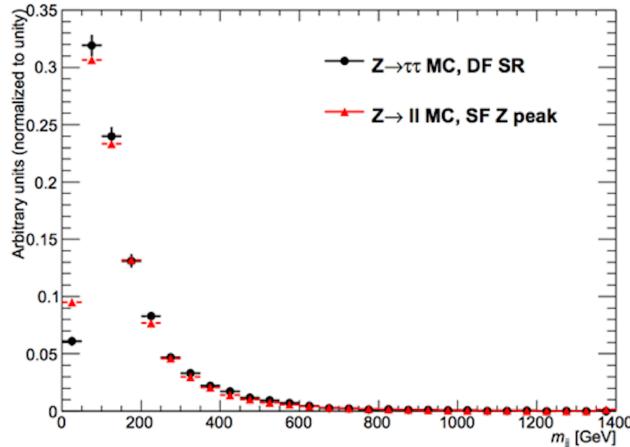

Figure 5.9: Comparison of m_{jj} shape in a same flavor $Z \rightarrow \ell\ell$ control region and the VBF cut-based signal region.
 The MC samples used for these distributions are given in table 5.4.

1998 Table 5.11 shows the overall normalization factor $\beta_{\tau\tau}$ and the efficiency correction factors for the various
 1999 VBF topological cuts. In general, the statistical uncertainties on the cut efficiency corrections are quite
 2000 good, and the MC tends to underestimate the efficiency of the VBF cuts for the $Z/\gamma^* \rightarrow \tau\tau$ background.
 2001 The overall normalization factor is also consistent with that calculated for the BDT analysis.

$\beta_{\tau\tau}$	0.97 ± 0.04
Cut	Correction factors (CF)
$m_{jj} > 600 \text{ GeV}$	1.09 ± 0.01
$\Delta y_{jj} > 3.6$	1.14 ± 0.02
CJV	1.20 ± 0.02
OLV	1.17 ± 0.03
$m_{jj} < 1 \text{ TeV}$	1.17 ± 0.06
$m_{jj} > 1 \text{ TeV}$	1.18 ± 0.13

Table 5.II: $Z/\gamma^* \rightarrow \tau\tau$ correction factors for the VBF cut-based analysis. Uncertainties are statistical only.

2002 5.5.4 $Z/\gamma^* \rightarrow \ell\ell$ BACKGROUND

2003 In the same flavor channels, the $Z/\gamma^* \rightarrow \ell\ell$ background is dominant and thus must be estimated cor-
 2004 rectly. In both the BDT and cut-based analyses, the background is estimated using the so-called “ABCD”
 2005 method. The ABCD method creates four different regions by defining requirements on two variables.
 2006 One of the regions (A) is the signal region, while the other regions are defined by inverting one of both of
 2007 the requirements. in this case, the two variables used are $m_{\ell\ell}$ and E_T^{miss} , because inverting either of the
 2008 SR cuts on these variables will give regions rich in the $Z/\gamma^* \rightarrow \ell\ell$ background. Figure 5.10 illustrates the
 2009 definitions of each region.

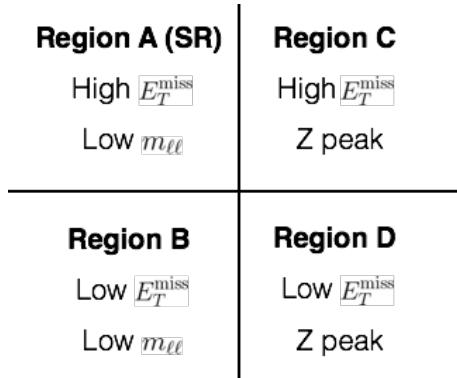

Figure 5.10: General illustration of the ABCD region definitions for $Z/\gamma^* \rightarrow \ell\ell$ background estimation.

2010 In both of the cut-based and BDT analyses, the Z peak region is defined with $|m_{\ell\ell} - m_Z| < 15 \text{ GeV}$.
 2011 In the cut-based analysis, low $m_{\ell\ell}$ corresponds to $m_{\ell\ell} < 50 \text{ GeV}$ (this defines the cut-based SR) while
 2012 in the BDT it is $m_{\ell\ell} < 75 \text{ GeV}$. In the cut-based, high and low E_T^{miss} are defined as opposite ends of

2013 the 55 GeV cut applied for the signal region definition. The BDT low E_T^{miss} region is between 25 and
 2014 45 GeV, while the high E_T^{miss} region is $E_T^{\text{miss}} > 45$ GeV.

2015 Once the regions are defined, the background in the signal region is estimated by extrapolating the
 2016 estimate in region B to region A. This extrapolation is done by multiplying the number of events in region
 2017 B by the ratio of the number of events in regions C and D. Effectively, the Z peak region is used to estimate
 2018 the efficiency of the E_T^{miss} requirement in data, and then this efficiency is applied in the low $m_{\ell\ell}$ region.
 2019 The method assumes that the E_T^{miss} efficiency is uncorrelated with $m_{\ell\ell}$. The method can be applied in
 2020 MC as a check on this assumption, and an additional correction, f_{corr} , is applied for the non-closure of
 2021 the method in MC. This is summarized in equations 5.6 and 5.7.

$$N_{Z/\gamma^* \rightarrow \ell\ell}^{\text{SR}} = N_{Z/\gamma^* \rightarrow \ell\ell}^{\text{B}} \times \frac{N_{Z/\gamma^* \rightarrow \ell\ell}^{\text{C}}}{N_{Z/\gamma^* \rightarrow \ell\ell}^{\text{D}}} \times f_{\text{corr}} \quad (5.6)$$

$$f_{\text{corr}} = \frac{B_{\text{MC}}^{\text{A}}/B_{\text{MC}}^{\text{B}}}{B_{\text{MC}}^{\text{C}}/B_{\text{MC}}^{\text{D}}} \quad (5.7)$$

2022 Here, the N refer to data yields in each region with the non Z/γ^* backgrounds subtracted, while B refer
 2023 to the Z/γ^* yields in MC in each region.

2024 A normalization factor $\beta_{\ell\ell}$ is computed for each analysis as the ratio of the predicted data yield to the
 2025 MC yield in the SR. The shape of the BDT distribution is taken from data region B, while the shape of
 2026 the m_T distribution in the cut-based analysis is taken from Z/γ^* MC in the SR. The values of $\beta_{\ell\ell}$ in the
 2027 cut-based and BDT analyses from this method are summarized in table 5.12. They are quite consistent
 2028 with one another within the statistical uncertainties. The value of f_{corr} is found to be 0.77 ± 0.13 . In the
 2029 cut-based analysis, the same cut efficiency correction factors shown in table 5.11 are also applied (in product
 2030 with the $\beta_{\ell\ell}$) to obtain the final estimate of the Z/γ^* background in the same flavor channels.

	$\beta_{\ell\ell}$
BDT Bin 1	1.01 ± 0.15
BDT Bin 2	0.89 ± 0.28
Cut-based	0.81 ± 0.21

Table 5.12: $Z/\gamma^* \rightarrow \ell\ell$ normalization factors for cut-based and BDT analyses. Uncertainties are statistical only.

2032 5.5.5 WW AND OTHER DIBOSON BACKGROUNDS

2033 The Standard Model WW and other diboson backgrounds (WZ , ZZ , $W\gamma$, $W\gamma^*$, and $Z\gamma$) have both
 2034 their shape and normalization taken from MC simulation as they are subdominant in the VBF analysis.
 2035 They are validated in dedicated control regions and found to agree with data well.

2036 As SM WW production is the largest of these backgrounds and is irreducible, validating the estimate
 2037 is of particular importance. A validation region is constructed by requiring the pre-selection requirements
 2038 on leptons and $m_{\ell\ell}, n_b = 0$, and $m_T > 100$ GeV. The m_{T2} variable is an additional discriminant that
 2039 has been shown to have the ability to isolate the SM WW background [99]. It is calculated by scanning
 2040 over all possible values of neutrino momentum for both W bosons and taking the minimum result. A
 2041 requirement of $m_{T2} > 160$ GeV is placed to define the WW validation region. This requirement gives a
 2042 60% purity for the validation region. The derived normalization factor in this region is 1.15 ± 0.19 and
 2043 is thus consistent with unity. Figure 5.11 shows the m_{T2} distribution and how it distinguishes the WW
 2044 background.

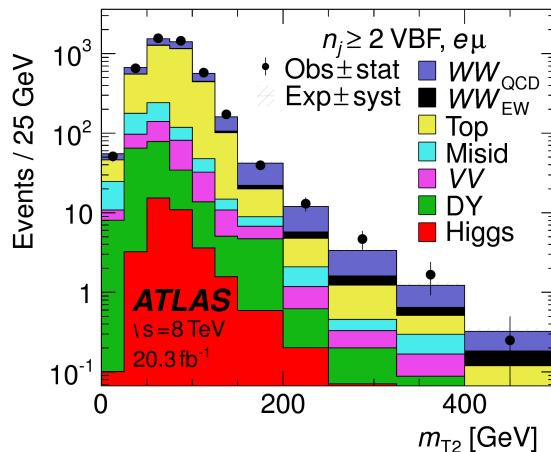

Figure 5.11: Distribution of m_{T2} in the WW validation region of the VBF analysis [74].

2045 5.5.6 HIGGS PRODUCTION VIA GLUON-GLUON FUSION

2046 Because this analysis is dedicated to measuring the VBF contribution to Higgs production, the component
 2047 of Higgs production from gluon-gluon fusion is treated as a background. The shape is taken directly from

2048 simulation, using the generators described in table 5.4. In the final combined fit of all different Higgs
2049 signal regions, the normalization is controlled by either a combined signal strength parameter μ , which
2050 controls the normalization of both ggF and VBF production, or a separate parameter μ_{ggF} depending on
2051 the interpretation being presented in the final results.

2052 5.5.7 BACKGROUNDS WITH MISIDENTIFIED LEPTONS

2053 As discussed previously, the $W+\text{jets}$ and QCD multijet backgrounds are derived with fully data-driven
2054 methods. These backgrounds do not make a large contribution to the final VBF signal region but their es-
2055 timation methods are discussed briefly here. Because both backgrounds involve at least one mis-identified
2056 lepton, they are labeled as “misid” throughout this chapter.

2057 $W+\text{jets}$ BACKGROUND

2058 The $W+\text{jets}$ background enters the signal region by having one of the jets mis-reconstructed as a lepton.
2059 The background is estimated by constructing a control sample with two leptons, where one lepton passes
2060 the usual lepton quality requirements but the second lepton fails one of those requirements (also known
2061 as the “anti-identified” lepton). This control region is rich in the $W+\text{jets}$ contribution because if a second
2062 lepton is reconstructed in a $W+\text{jets}$ event it is likely to be of poor quality. The purity of this $W+\text{jets}$ control
2063 sample is 85% to 90% depending on the exact configuration of leptons in the final state.

2064 The $W+\text{jets}$ content of the signal region is estimated by extrapolation from the control sample to the
2065 signal region using extrapolation factors derived in a $Z+\text{jets}$ control sample in data. The assumption of
2066 the method is that the probability of a jet being misidentified as a lepton does not change between $W+\text{jets}$
2067 and $Z+\text{jets}$ samples, and systematic uncertainties are assigned for differences in sample composition. The
2068 extrapolation factor is defined as the ratio of the number of lepton candidates satisfying all quality criteria
2069 to the number of lepton candidates anti-identified. This ratio is measured in bins of p_T and η . Thus, the
2070 final signal region estimate (binned as the extrapolation factor is binned) is simply the number of events in
2071 the anti-identified lepton control sample multiplied by the extrapolation factor derived from the $Z+\text{jets}$
2072 control sample. Figure 5.12 shows the extrapolation factors derived for electrons and muons. The extrap-

2073 olation factor can be seen in the figure to be an order of magnitude larger for muons than electrons, but
 2074 this does not indicate that jets have a larger probability to be mis-identified as a muon than an electron.
 2075 Values of the extrapolation factor are actually determined by the specific requirements used to define an
 2076 anti-identified lepton. The difference between the muon and electron extrapolation factors comes from
 2077 different definitions of the anti-identified lepton in each case.

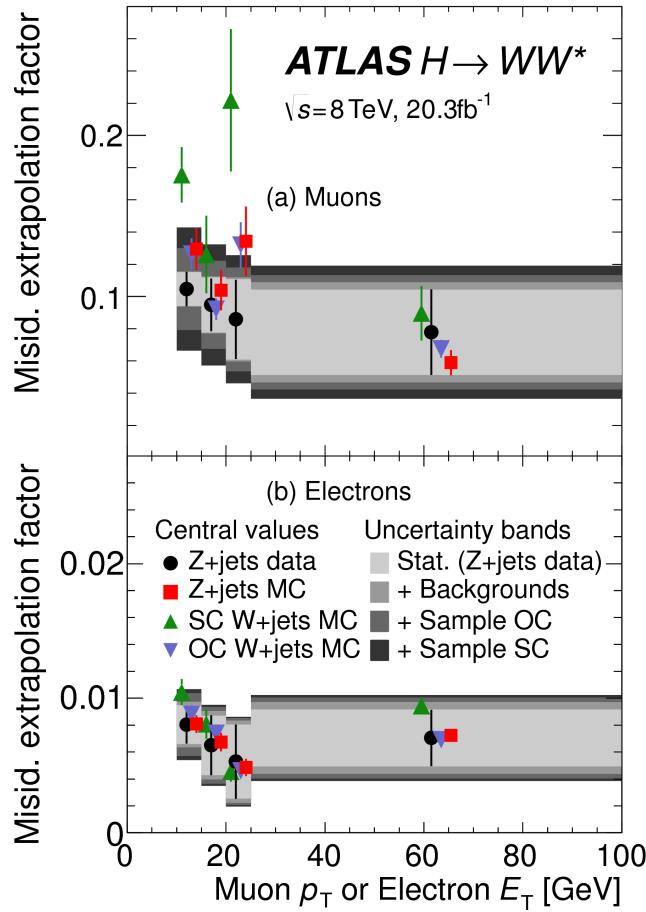

Figure 5.12: Extrapolation factors for the $W + \text{jets}$ estimate derived for muons (a) and electrons (b) as a function of lepton p_T [74]. OC refers to the opposite charge $W + \text{jets}$ MC sample, while SC refers to the same charge $W + \text{jets}$ MC. The uncertainty bands have contributions from statistical uncertainty in the data and backgrounds to $Z + \text{jets}$ that are subtracted from the data, as well as systematic uncertainties due to variations in the extrapolation factor between the three MC samples shown.

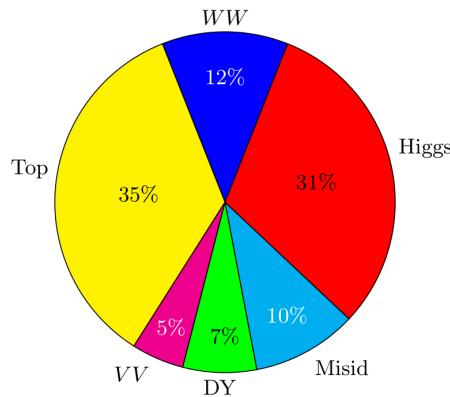

2078 **QCD MULTIJET BACKGROUND**

2079 The method for estimating the multijet background is very similar to the $W + \text{jets}$ estimation method. The
2080 control sample in this case has two anti-identified leptons but otherwise satisfies all signal region require-
2081 ments. The extrapolation factor is estimated from a multijet sample and applied twice to the control sam-
2082 ple.

2083 **5.5.8 BACKGROUND COMPOSITION IN SIGNAL REGION**

2084 After all of these estimation procedures, the signal region background composition can be calculated. The
2085 estimated yields are all shown in table 5.8. Figure 5.13 shows the relative percentages of the different back-
2086 ground for the different flavor and same flavor final states. In $e\mu$, the leading backgrounds are top back-
2087 grounds, ggF Higgs, and SM WW production. In $ee/\mu\mu$, the leading background is Drell-Yan, followed
2088 by top and ggF Higgs.

(a) $n_j \geq 2$ VBF, $e\mu$

(b) $n_j \geq 2$ VBF, $ee/\mu\mu$

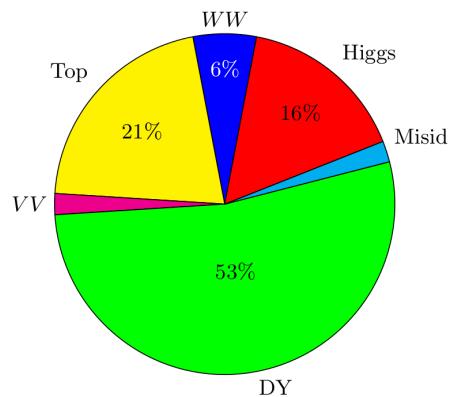

Figure 5.13: Background composition in final VBF signal region [74].

2089 **5.6 SYSTEMATIC UNCERTAINTIES**

2090 There are two main types of systematic uncertainties that are assessed for the analysis. First, theoretical
2091 uncertainties associated with the signal and background yield estimates are discussed. Then, experimental
2092 uncertainties due to detector effects are shown. Normalization uncertainties refer to uncertainties that

2093 affect the cross section of the process in question in the signal region being probed. Shape uncertainties
2094 refer to systematic uncertainties that affect the shape of the final discriminating variable (either m_T or
2095 O_{BDT}).

2096 **5.6.1 THEORETICAL UNCERTAINTIES**

2097 There are four main components to theoretical uncertainties assigned to signal and background processes
2098 taken from Monte Carlo. Each one is a different source of variation in the overall acceptance for that
2099 process. The first involves variation of the QCD renormalization and factorization scales used in the cal-
2100 culation. In this case, the two scales are varied both independently and simultaneously by factors of two
2101 high or low. The resulting variation in normalization and shape for the process is taken as a systematic
2102 uncertainty (referred to as scale uncertainty). This uncertainty approximates the level of the correction
2103 to the cross section that would come from including the next order of the QCD calculation. Next, there
2104 is an uncertainty associated with the PDF set used in generating the events. The uncertainty eigenvec-
2105 tors for the given PDF set are inspected, and the envelope of maximal variation is taken as an uncertainty
2106 (referred to as PDF uncertainty). Finally, there are two uncertainties associated with the choice of MC
2107 software. An uncertainty associated with the generator chosen for the hard scattering process is evaluated
2108 by keeping the parton showering software constant but varying the matrix element generator and taking
2109 the maximal variation as an uncertainty (referred to as the generator uncertainty). The converse variation
2110 can also be done, where the matrix element generator remains constant and the generator used for the un-
2111 derlying event/parton shower modeling is varied (referred to as the UE/PS uncertainty). In cases where
2112 the background is normalized in a control region, the systematic uncertainty arises from variations of the
2113 extrapolation factor α between the CR and the SR, which can affect the normalization of the background
2114 in the SR.

2115 There are two additional uncertainties that are applied to the Higgs processes as well. First, there are
2116 uncertainties assigned to the Higgs total production cross section. Then, there are uncertainties assigned
2117 based on the fact that the analysis is done in exclusive jet bins and it is possible for signal events to migrate
2118 from one bin to the next depending on the presence or absence of jets. These are assigned using the Jet Veto

2119 Efficiency (JVE) procedure [18, 100] for ggF events and the Stewart-Tackmann (ST) method [101] for VBF
 2120 production. Table 5.13 shows the total theory uncertainties on the backgrounds in the cut-based analysis.
 2121 These are the sum in quadrature of the uncertainties from each of the variations described above.

Process	Theory syst. (%)
ggF H	48
Top	26
QCD WW	37
$Z/\gamma^* \rightarrow \tau\tau$	6.1

Table 5.13: Systematic uncertainties for various processes in the cut-based VBF analysis, given in units of % change in yield. Values are given for the low m_{jj} signal region.

2122 Figures 5.14 and 5.15 show the variations in the extrapolation factor from the PDF and QCD uncertain-
 2123 ties on the top background estimate, binned in m_T , for the cut-based analysis. In both cases, there was
 2124 no significant shape uncertainty but normalization uncertainties were assigned according to the maximal
 2125 variation. These uncertainties enter into the 26% total uncertainty on top quark production quoted in
 2126 table 5.13

2127 While the estimate for the same-flavor $Z/\gamma^* \rightarrow \ell\ell$ background is data-driven, there is still a systematic
 2128 uncertainty taken for the non-closure of the method in Monte Carlo. This is taken as the maximum of the
 2129 deviation of the non-closure factor f_{corr} from unity and its uncertainty, or $\max(|1 - f_{\text{corr}}|, \delta f_{\text{corr}})$. For
 2130 the cut-based analysis this non-closure uncertainty 23%, while for the BDT analysis it is 17%.

2131 5.6.2 EXPERIMENTAL UNCERTAINTIES

2132 In this analysis, the theoretical uncertainties are the most dominant after statistical, but there are some ex-
 2133 perimental uncertainties that make a contribution as well. The first is the uncertainty on the measured in-
 2134 tegrated luminosity, which affects backgrounds whose normalizations are taken from MC and is measured
 2135 to be 2.8% in the 8 TeV dataset [102]. The dominant sources of uncertainty overall are uncertainties on the
 2136 jet energy scale and resolution and the b -tagging efficiency. Additional sources include lepton uncertain-
 2137 ties on identification, resolution, and trigger efficiency, as well as uncertainties on the missing transverse
 2138 momentum.

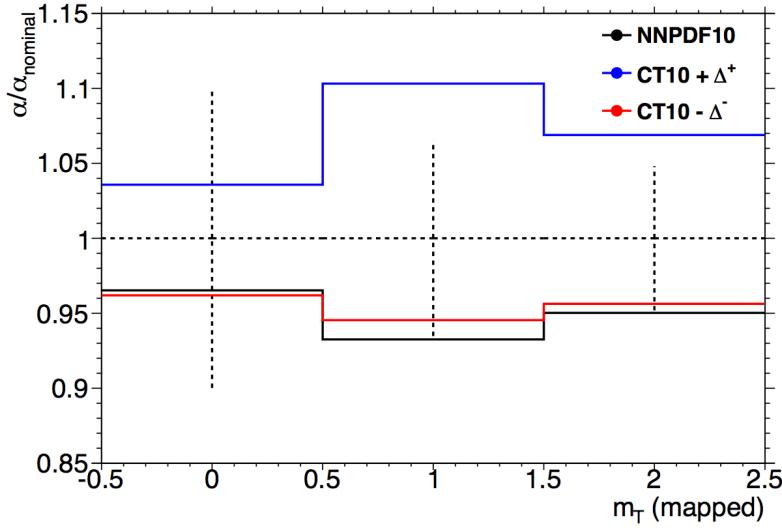

Figure 5.14: Variations in the top background extrapolation factor in the cut-based analysis due to PDF uncertainties. The uncertainties are shown in the three bins of m_T used in the final cut-based statistical fit. Variations from the eigenvector of the nominal PDF, CT10, as well as the result from an alternate PDF (NNPDF10), are compared.

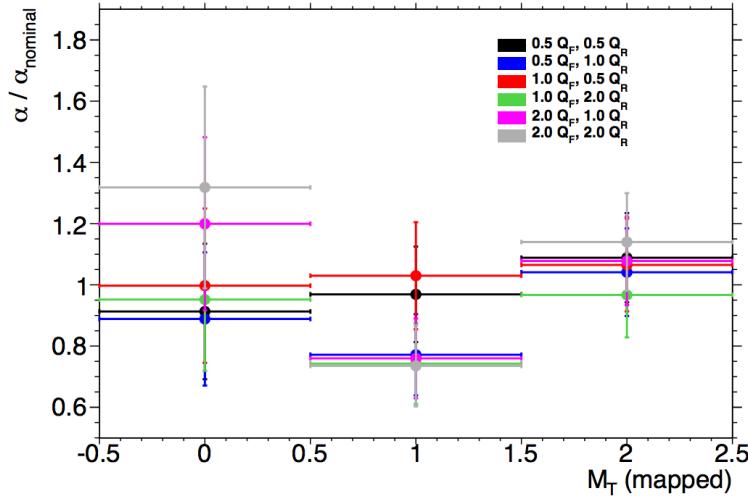

Figure 5.15: Variations in the top background extrapolation factor in the cut-based analysis due to QCD scale uncertainties. The uncertainties are shown in the three bins of m_T used in the final cut-based statistical fit. Q_F is the QCD factorization scale, while Q_R is the QCD renormalization scale.

The jet energy scale uncertainty is split into several independent components, including jet-flavor dependent calorimeter response uncertainties, uncertainties on modeling of pile-up interactions, uncertainties on extrapolation from the central to forward detector regions, and MC non-closure [103]. The uncer-

Sample	Total error	Stat. error	Expt. syst. err.	Theo. syst. err.

Table 5.14: Composition of the post-fit uncertainties (in %) on the total signal (N_{sig}), total background (N_{bkg}), and individual background yields in the VBF analysis [74].

tainty on energy scale for jets used in this analysis ranges from 1% to 7% depending on the jet p_{T} and η .
The jet energy resolution varies from 5% to 20%, with uncertainties ranging from 2% to 40% (the largest uncertainties occurring at the selection threshold).

The b-tagging efficiency is independently measured in data samples enriched in dileptonic decays of $t\bar{t}$ events or in events where a muon is reconstructed in the vicinity of a jet [104, 105]. The efficiencies and their uncertainties are binned in p_{T} and decomposed into uncorrelated components using an eigenvector method [106]. Uncertainties on the efficiency range from 1% to 7.8%. The uncertainty on the rate of misidentification of c -jets as b -jets ranges from 6-14%, while the uncertainty on the rate of light jet mis-tagging ranges from 9-19% depending on p_{T} and η .

The total experimental uncertainties on different signal and background components are summarized in table 5.14. They are compared to the level of other statistical and systematic uncertainties as well. Overall, the experimental uncertainties are sub-dominant compared to the statistical and theoretical uncertainties.

5.7 RESULTS

While the combined results of all the $H \rightarrow WW^*$ sub-analyses will be discussed in the next chapter, this section presents the results of the VBF specific analysis and interpretations. As table 5.7 shows, the final cut-based signal region contains 20 events in data with $m_{\text{T}} < 150$ GeV, 14 coming from the $e\mu$ channel

and 6 coming from the $ee + \mu\mu$ channel. The BDT analysis has many more candidates due to its looser selection, and the yields in each bin of O_{BDT} are shown in table 5.15.

Table 5.15: Event selection for the VBF BDT analysis. The event yields in (a) are shown after the pre-selection and the additional requirements applied before the BDT classification (see text). The event yields in (b) are given in bins in O_{BDT} after the classification [74].

Figure 5.16(a) shows the final distribution of data candidates compared to the expected m_T distribution for signal and background. The data are very consistent with a VBF Higgs hypothesis. Figure 5.16(b) shows where the data candidates fall in the two-dimensional binning of m_T and m_{jj} used in the fit for the cut-based analysis. Figure 5.17 shows the distributions of O_{BDT} and m_T in the VBF BDT analysis. Again the data are quite consistent with a VBF Higgs hypothesis.

Because the cut-based result is used as a validation for the BDT analysis and the two signal regions are not fully orthogonal, it is interesting to explore which events overlap between the two analyses. Of the twenty events in the cut-based signal region, only seven were not selected by the BDT analysis, while the other thirteen also enter the BDT signal region. Figure 5.18 shows where the different analysis candidates lie in the m_{jj} - m_T plane. This shows clearly that the advantage of the BDT analysis is that it can extract signal candidates from the lower m_{jj} region due to its ability to recognize correlations with other variables.

While the context of these results in the broader $H \rightarrow WW^*$ statistical analysis will be presented in the next chapter, the statistical significance of the VBF Higgs result is shown here. In the BDT analysis, the

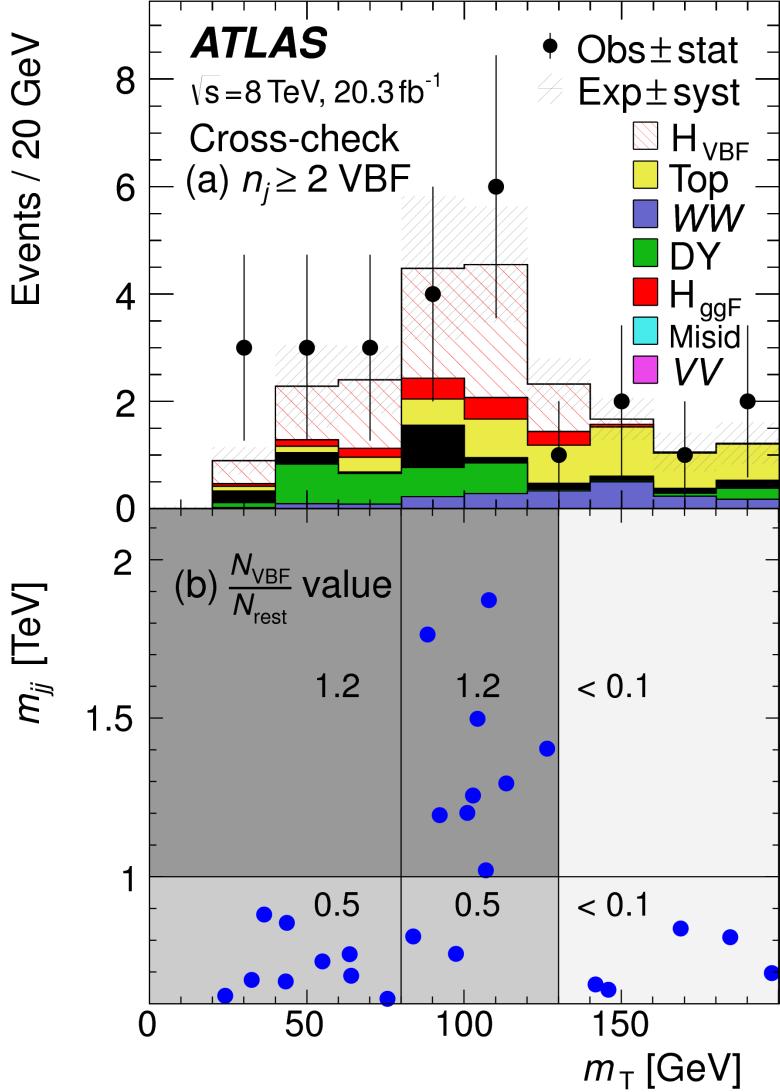

Figure 5.16: Post-fit distributions in the cut-based VBF analysis. Panel (a) shows the one-dimensional m_T distribution, while (b) shows the data candidates split into the bins of m_T and m_{jj} used in the final fit [74].

expected signal significance was 2.7σ , while the observed significance was 3.1σ . In the cut-based analysis, the expected significance was 2.1σ and the observed significance was 3.0σ . The compatibility between these two results can be evaluated by computing the probability of observing a larger difference in Z_0 values than the one measured. Using toy Monte Carlo with the ggF signal strength fixed to unity and considering only statistical uncertainties, this probability is computed to be 79%, indicating good agreement between the analyses. This result represents the first evidence of the vector boson fusion production of a Higgs

6.1 INTRODUCTION

2184 2185 2186 2187 2188 2189 2190

In the final statistical analysis of $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$, the dedicated gluon-gluon fusion and vector boson fusion sensitive signal regions are all combined into a single fit to determine the main parameters of interest, the Higgs signal strength μ and mass m_H . Therefore, while the specific requirements applied for the VBF sensitive analysis are discussed in chapter 5, the final measurement of these parameters can only be discussed in combination with the results of the ggF dedicated analysis. For example, because ggF Higgs production is considered a background in the VBF analysis, the ggF dedicated signal regions can actually constrain the normalization of this background in the VBF dedicated region.

2191

This chapter presents the combined interpretation of results in the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis

2192 for gluon fusion and vector boson fusion Higgs production. First, the results of the dedicated gluon fu-
 2193 sion search are presented. Then, a comparison of the individual production mode signal strengths (μ_{ggF}
 2194 and μ_{VBF}) and a measurement of the combined signal strength (μ) are shown. Subsequently, the mea-
 2195 sured values of the Higgs couplings to fermions and vector bosons is presented. Finally, the cross section
 2196 measurement for ggF and VBF production are shown.

2197 6.2 RESULTS OF DEDICATION GLUON FUSION $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ ANALYSIS

2198 The details of the dedicated gluon fusion $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis are not discussed in this thesis
 2199 and instead left to more comprehensive sources [74]. However, a brief summary of the results is essen-
 2200 tial for describing the measurements of Higgs properties and interpreting the the dedicated VBF Higgs
 2201 production search in a broader context. Additionally, the final Run 1 results on gluon fusion production
 2202 make use of the dedicated variables for same flavor final states developed in section 3.5. The results in the
 2203 same flavor final states will be shown here as well.

2204 6.2.1 RESULTS IN SAME FLAVOR ($ee/\mu\mu$) FINAL STATES

2205 Final states of the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel where both leptons have the same flavor ($ee/\mu\mu$)
 2206 were not included in the discovery result due to increased pileup conditions in the $\sqrt{s} = 8$ TeV data.
 2207 Dedicated techniques for background reduction in the same flavor final states were developed, as described
 2208 in section 3.5. The results shown in this section are the first published results using the same flavor channels
 2209 in the $H \rightarrow WW^*$ analysis.

2210 Table 6.1 shows the background estimate, expected signal yield, and event count in data for the same
 2211 flavor channels in the $n_j \leq 1$ signal regions. The dedicated same flavor background reduction techniques
 2212 allow this channel to preserve a signal to background ratio similar to that of the different flavor channels.

	N_{obs}	N_{bkg}	N_{ggF}	N_{VBF}
$n_j = 0$	1108	1040 ± 40	77 ± 15	2.4 ± 1.7
$n_j = 1$	467	427 ± 21	22 ± 6	3.6 ± 1.8

Table 6.1: Post-fit yields in ggF dedicated signal regions for the $ee/\mu\mu$ final states [74].

2213 Figure 6.1 shows the final m_T distribution in data for the $n_j \leq 1$ same flavor channels. The data is very
 2214 consistent with the Higgs hypothesis and it can be seen that the same flavor channels are indeed sensitive
 2215 to gluon fusion production of the Higgs.

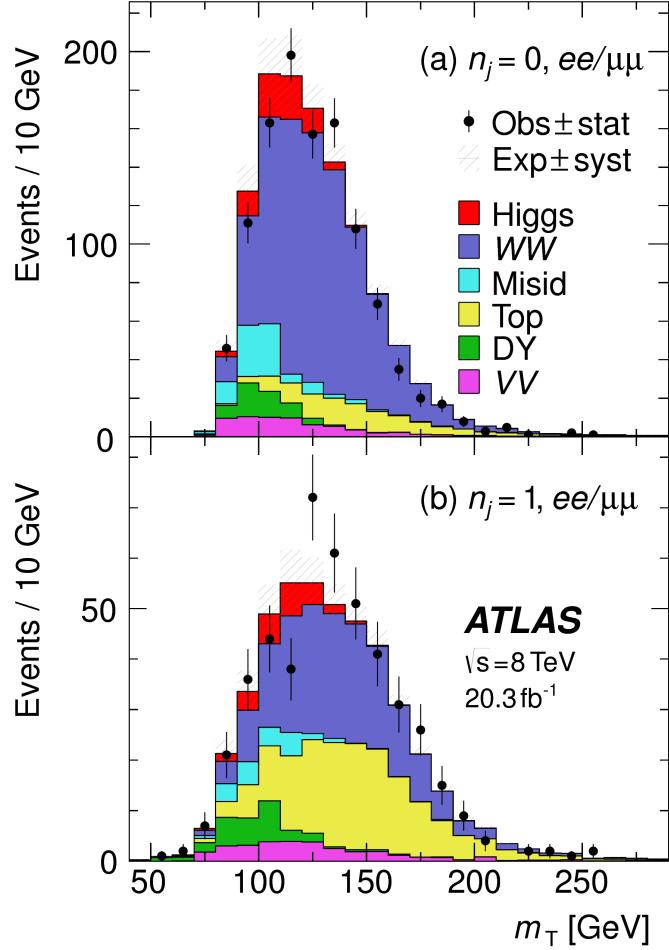

Figure 6.1: Post-fit m_T distribution in the $n_j \leq 1$ regions for the same flavor ($ee/\mu\mu$) final states [74].

2216 6.2.2 COMBINED GLUON FUSION RESULTS

2217 Table 6.2 shows the individual signal regions that were input into the final statistical fit. The ggF dedicated
 2218 bins use m_T as their discriminating variable and are separated into bins of p_T of the subleading lepton as
 2219 well. The VBF dedicated bin uses the O_{BDT} distribution as its final discriminant.

2220 Table 6.3 shows the yields in the various signal regions in both data and expected signal and back-
 2221 grounds. The yields for signal and background are all scaled according to the final normalizations cal-

SR category i				Fit var.

$n_j \geq 2$, VBF	130	99 ± 9	7.7 ± 2.6	21 ± 3

Table 6.3: Post-fit yields in the both ggF and VBF dedicated signal regions with all lepton flavor final states combined [74].

Figure 6.2 shows the final post-fit m_T distribution in the $n_j \leq 1$ regions. The data are very consistent with the hypothesis of ggF Higgs production. These yields are used as input, along with the VBF results in chapter 5, for the physical interpretation of results presented in subsequent sections.

6.3 SIGNAL STRENGTH MEASUREMENTS IN GGF AND VBF PRODUCTION

When all of the signal regions are combined in the fit, there can be a combined measurement of the signal strength as well as the individual ggF and VBF signal strengths. The combined signal strength is the ratio of the measured cross section in the combined gluon fusion and VBF signal regions to the theory prediction

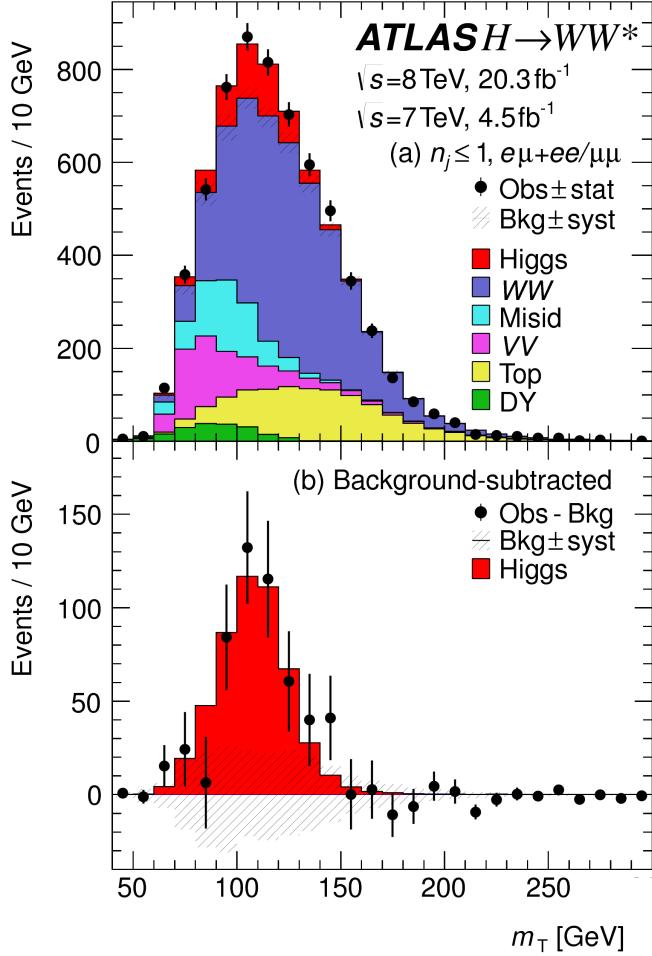

Figure 6.2: Post-fit m_T distribution in the $n_j \leq 1$ regions [74].

for the sum of of these two processes. It is a signal strength measurement for the total Higgs production cross section that this analysis is sensitive to. The final measured combined signal strength μ is measured shown in equation 6.1.

$$\begin{aligned}
 \mu &= 1.09 \quad {}^{+0.16}_{-0.15} (\text{stat.}) \quad {}^{+0.08}_{-0.07} \left(\frac{\text{expt}}{\text{syst}} \right) \quad {}^{+0.15}_{-0.12} \left(\frac{\text{theo}}{\text{syst}} \right) \quad \pm 0.03 \left(\frac{\text{lumi}}{\text{syst}} \right) \\
 &= 1.09 \quad {}^{+0.16}_{-0.15} (\text{stat}) \quad {}^{+0.17}_{-0.14} (\text{syst}) \\
 &= 1.09 \quad {}^{+0.23}_{-0.21}.
 \end{aligned} \tag{6.1}$$

2233 Figure 6.3 gives the best fit signal strength $\hat{\mu}$ as a function of the hypothesized Higgs mass. The value at
 2234 a mass of 125.36 GeV corresponds to the μ quoted in equation 6.1. This value of the Higgs mass is used
 2235 because it is the most precise mass measurement from ATLAS, a result of the combined $\gamma\gamma$ and ZZ mass
 2236 measurements [107].

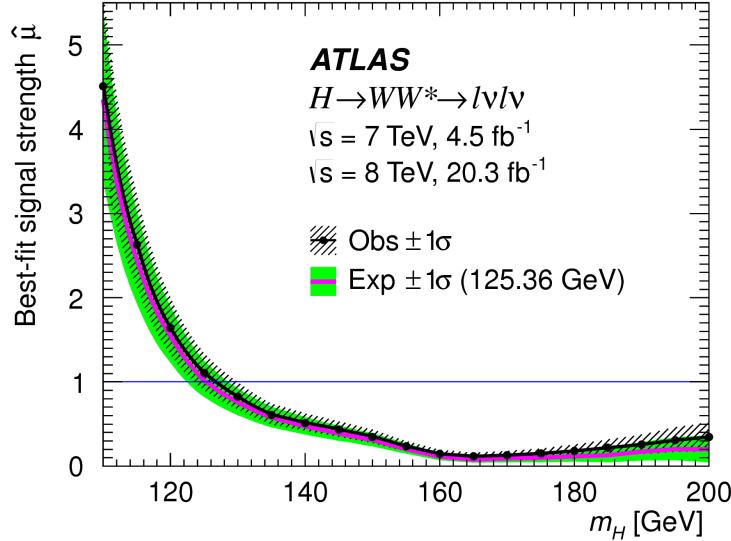

Figure 6.3: Best fit signal strength $\hat{\mu}$ as a function of hypothesized m_H [74].

2237 As explained in chapter 3, a probability p_0 can be computed using the test statistic q_0 to quantify the
 2238 probability that the background could fluctuate to produce an excess at least as large as the one observed
 2239 in the data. The local p_0 value is shown in figure 6.4 as a function of m_H . The minimum p_0 value is at
 2240 $m_H = 130$ GeV and corresponds to a significance of 6.1σ . The curve is relatively flat and the significance
 2241 is the same at 125.36 GeV within the quoted precision. The expected significance for a signal with strength
 2242 $\mu = 1.0$ is 5.8σ . This represents the first discovery level observation of Higgs production using only the
 2243 $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ analysis.

2244 All the results presented so far in this section have been for the combined gluon fusion and VBF pro-
 2245 duction modes. However, each signal strength can be calculated separately in the likelihood as well. There
 2246 are two ways to do this. First, the likelihood can be parameterized in terms of a single parameter, the ratio
 2247 of the VBF and gluon fusion signal strengths. With this method, the statistical significance of the VBF
 2248 Higgs result can be evaluated. Figure 6.5 shows the likelihood as a function of the ratio $\mu_{\text{VBF}}/\mu_{\text{ggF}}$.

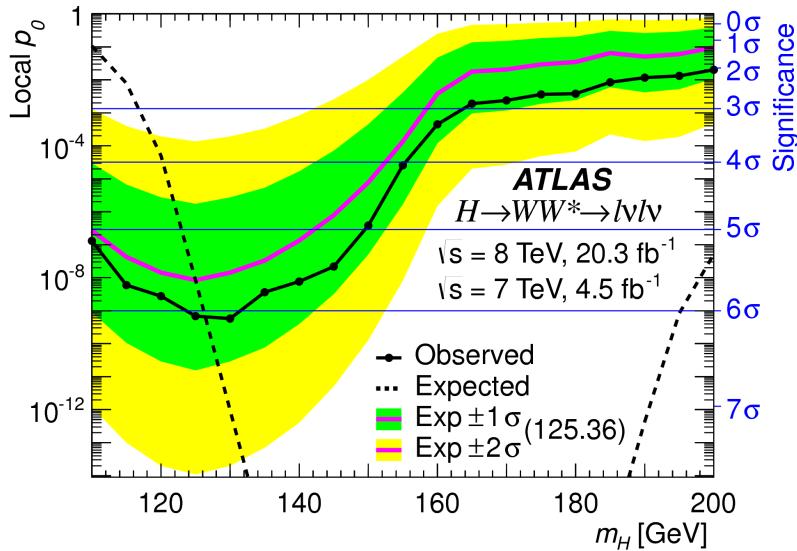

Figure 6.4: Local p_0 as a function of m_H [74].

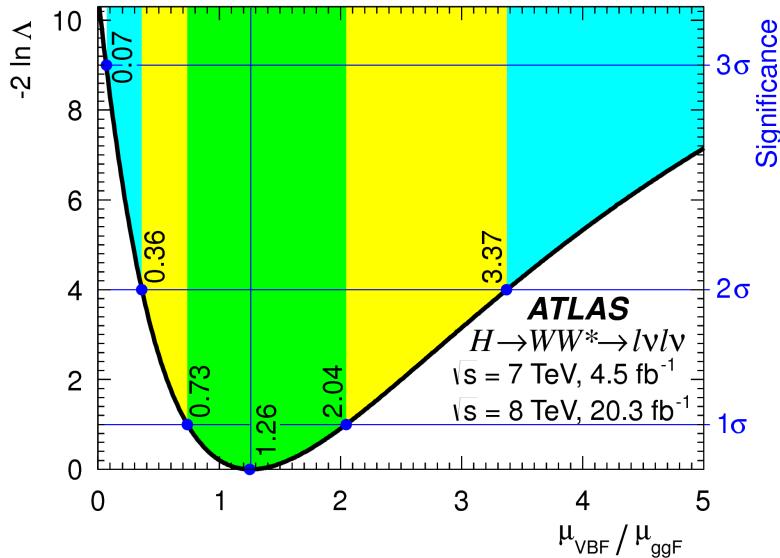

Figure 6.5: Likelihood as a function of $\mu_{\text{VBF}} / \mu_{\text{ggF}}$ [74].

2249 The best fit value of the ratio of signal strengths is shown in equation 6.2. Within the quoted uncer-
2250 tainties, it is consistent with a ratio of unity.

$$\frac{\mu_{\text{VBF}}}{\mu_{\text{ggF}}} = 1.26^{+0.61} (\text{stat.})^{+0.50} (\text{syst.}) = 1.26^{+0.79}_{-0.53} \quad (6.2)$$

2251 The null hypothesis for VBF production corresponds to a ratio of $\mu_{\text{VBF}}/\mu_{\text{ggF}} = 0$. The likelihood in
 2252 figure 6.5 gives a significance of 3.2σ at $\mu_{\text{VBF}}/\mu_{\text{ggF}} = 0$, as quoted in chapter 5.

2253 In addition to the ratio of signal strengths, each signal strength can be varied independently in the like-
 2254 lihood as well. Figure 6.6 shows the two dimensional likelihood scan in the $\mu_{\text{ggF}}-\mu_{\text{VBF}}$ plane. The best fit
 2255 values of the two signal strengths are shown in equation 6.3. Both are consistent with unity within their
 2256 uncertainties.

$$\begin{aligned} \mu_{\text{ggF}} &= 1.02 \pm 0.19^{+0.22}_{-0.18} = 1.02^{+0.29}_{-0.26} \\ \mu_{\text{VBF}} &= 1.27^{+0.44}_{-0.40}^{+0.29}_{-0.21} = 1.27^{+0.53}_{-0.45} \end{aligned} \quad (6.3)$$

(stat.) (syst.)

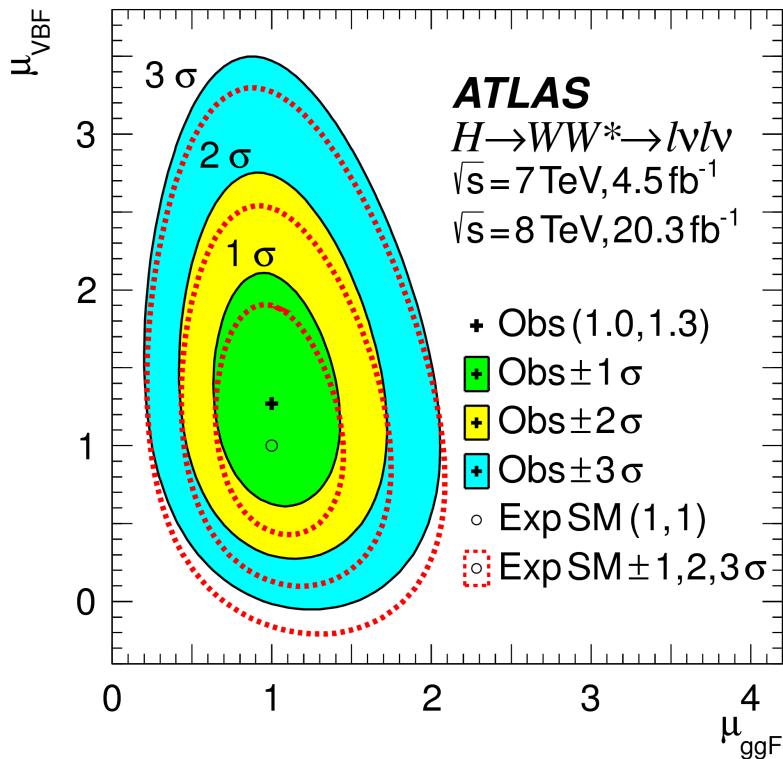

Figure 6.6: Two dimensional likelihood scan as a function of μ_{VBF} and μ_{ggF} [74].

2257 6.4 MEASUREMENT OF HIGGS COUPLINGS TO VECTOR BOSONS AND FERMIONS

2258 Similar to the parameterization of signal strength, the couplings of the Higgs to fermions and bosons can
 2259 also be parameterized. The parameter of interest in this case is κ , or the ratio of the measured coupling to
 2260 the Standard Model expectation. Both the fermion and boson couplings have these so-called scale factors,
 2261 κ_F for fermions and κ_V for bosons. Gluon fusion production is sensitive to the fermion couplings through
 2262 the top quark loops in its production, while VBF production is sensitive to the vector boson couplings in
 2263 its production. Both modes are sensitive to the vector boson couplings in their decays. The signal strengths
 2264 will have dependence on the coupling scale factors as described in equation 6.4 [18].

$$\begin{aligned}\mu_{\text{ggF}} &\propto \frac{\kappa_F^2 \cdot \kappa_V^2}{(\mathcal{B}_{H \rightarrow f\bar{f}} + \mathcal{B}_{H \rightarrow gg}) \kappa_F^2 + (\mathcal{B}_{H \rightarrow VV}) \kappa_V^2} \\ \mu_{\text{VBF}} &\propto \frac{\kappa_V^4}{(\mathcal{B}_{H \rightarrow f\bar{f}} + \mathcal{B}_{H \rightarrow gg}) \kappa_F^2 + (\mathcal{B}_{H \rightarrow VV}) \kappa_V^2}.\end{aligned}\quad (6.4)$$

2265 Figure 6.7 shows the two-dimensional likelihood scan of κ_F and κ_V . The best-fit values are given in equa-
 2266 tion 6.5. The best-fit values are consistent with unity within their uncertainties.

$$\begin{aligned}\kappa_F &= 0.93 & {}^{+0.24}_{-0.18} & {}^{+0.21}_{-0.14} & = 0.93 & {}^{+0.32}_{-0.23} \\ \kappa_V &= 1.04 & {}^{+0.07}_{-0.08} & {}^{+0.07}_{-0.08} & = 1.04 & \pm 0.11.\end{aligned}\quad (6.5)$$

(stat.) (syst.)

2267

2268 6.5 HIGGS PRODUCTION CROSS SECTION MEASUREMENT

2269 Another measurement that comes naturally from the signal strength measurements quoted earlier is the
 2270 production cross section and 7 and 8 TeV for both gluon fusion and VBF production. The general equa-

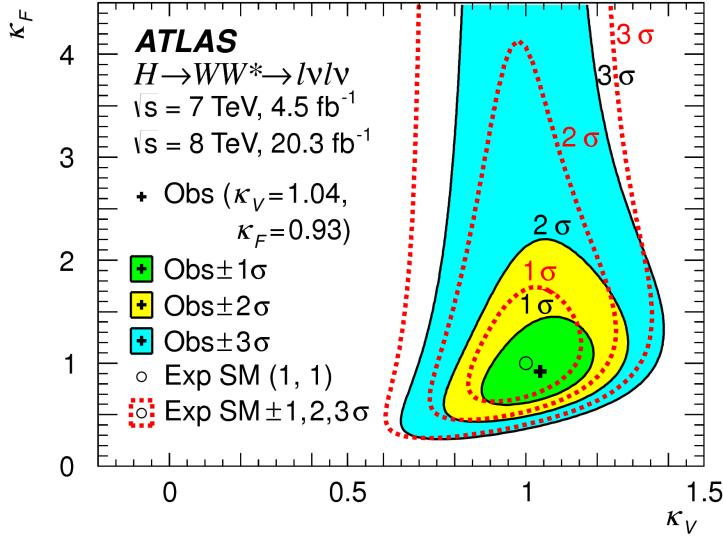

Figure 6.7: Likelihood scan as a function of κ_F and κ_V , the Higgs coupling scale factors [74].

tion for calculating the cross section is given in equation 6.6.

$$\begin{aligned}
 (\sigma \cdot \mathcal{B}_{H \rightarrow WW^*})_{\text{obs}} &= \frac{(N_{\text{sig}})_{\text{obs}}}{\mathcal{A} \cdot \mathcal{C} \cdot \mathcal{B}_{WW \rightarrow l\bar{l}l\nu}} \cdot \frac{1}{\int L dt} \\
 &= \hat{\mu} \cdot (\sigma \cdot \mathcal{B}_{H \rightarrow WW^*})_{\text{exp}}
 \end{aligned} \tag{6.6}$$

$(N_{\text{sig}})_{\text{obs}}$ is the number of events observed in data. \mathcal{A} is the geometric and kinematic acceptance of the detector, while \mathcal{C} is the efficiency of the signal region selection for events that are reconstructed in the detector. The branching ratio of a WW system to leptons must also be divided out. The production cross section depends on the center of mass energy and the production mode desired (gluon fusion or VBF), and so three separate cross section measurements are quoted in equation 6.7.

$$\begin{aligned}
 \sigma_{\text{ggf}}^{7\text{TeV}} \cdot \mathcal{B}_{H \rightarrow WW^*} &= 2.0 \pm 1.7 \quad {}^{+1.2}_{-1.1} = 2.0 \quad {}^{+2.1}_{-2.0} \text{ pb} \\
 \sigma_{\text{ggf}}^{8\text{TeV}} \cdot \mathcal{B}_{H \rightarrow WW^*} &= 4.6 \pm 0.9 \quad {}^{+0.8}_{-0.7} = 4.6 \quad {}^{+1.2}_{-1.1} \text{ pb} \\
 \sigma_{\text{VBF}}^{8\text{TeV}} \cdot \mathcal{B}_{H \rightarrow WW^*} &= 0.51 \quad {}^{+0.17}_{-0.15} \quad {}^{+0.13}_{-0.08} = 0.51 \quad {}^{+0.22}_{-0.17} \text{ pb.}
 \end{aligned} \tag{6.7}$$

(stat.) (syst.)

2277 The predicted cross section values (including the branching ratio of $H \rightarrow WW^*$) for gluon fusion are
2278 3.3 ± 0.4 pb at 7 TeV and 4.2 ± 0.5 pb at 8 TeV, consistent with the measured values within their uncer-
2279 tainties. For vector boson fusion, the predicted cross section is 0.35 ± 0.02 pb, again consistent with the
2280 measured value.

2281 **6.6 CONCLUSION**

2282 The combined analysis of the gluon fusion and vector boson fusion processes in $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ in
2283 the 7 and 8 TeV datasets has yielded the first discovery level significance for Higgs production in this decay
2284 channel. Additionally, precise measurements of the couplings to vector bosons and fermions are given.
2285 Finally, signal strengths and cross sections for each production mode are measured. Figure 6.8 shows the
2286 $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ measurements in comparison with other Higgs decay channels in ATLAS. The
2287 measurement of signal strength from this channel remains the most sensitive in both the gluon fusion and
2288 VBF production modes for the Run 1 dataset.

2296

7.1 INTRODUCTION

2297 This chapter presents a search for resonant production of a Higgs pair in the $X \rightarrow HH \rightarrow b\bar{b}b\bar{b}$ final
2298 state in 3.2 fb^{-1} of data collected at $\sqrt{s} = 13 \text{ TeV}$. In particular, this chapter focuses on a search for this
2299 final state in the regime where m_X is large ($\gtrsim 1 \text{ TeV}$) and the Higgs bosons in the decay are significantly
2300 boosted. A tailored selection for this boosted selection, using novel techniques in jet substructure and b -
2301 tagging, is discussed. Then, the data-driven background estimate is presented. Finally, the results of the
2302 search are shown. The signal models used as benchmarks are a spin-2 Randall Sundrum graviton (RSG)
2303 and a narrow width spin zero resonance. These models are described in more detail in Chapter 1. Limits
2304 on signal models are reserved for the next chapter where the results of this chapter are combined with the

2305 results of a separate selection dedicated to the lower m_X regime.

2306 **7.2 MOTIVATION**

2307 With the center of mass energy increase from $\sqrt{s} = 8 \text{ TeV}$ to $\sqrt{s} = 13 \text{ TeV}$, the LHC and ATLAS are
2308 able to probe new resonances at higher mass scales than previously accessible in Run 1. This is a powerful
2309 motivator for searching for a new resonance in the early 13 TeV data. Figure 7.1 shows the ratios of parton
2310 luminosities between 8 and 13 TeV for different resonance masses. For a resonance of $M_X = 2 \text{ TeV}$, the
2311 cross section at $\sqrt{s} = 13 \text{ TeV}$ is roughly a factor of 10 larger than at $\sqrt{s} = 8 \text{ TeV}$.

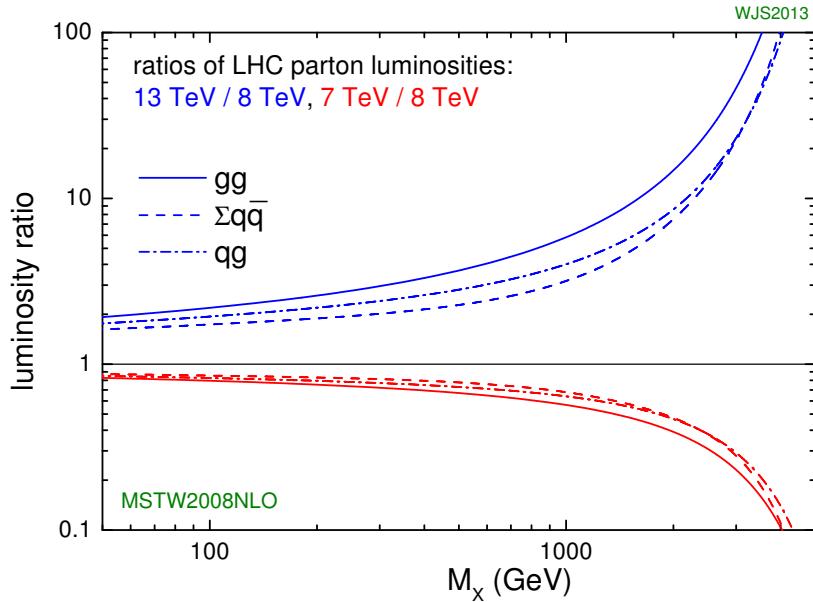

Figure 7.1: Parton luminosity ratios as a function of resonance mass M_X for 13/8 TeV and 7/8 TeV [109].

2312 Higgs pair production offers a vast array of unprobed regions of phase space where searches for BSM
2313 physics can be made. Chapter 1 discusses some possibilities for both resonant and non-resonant enhance-
2314 ment of the di-Higgs production cross section. Given the increased mass reach of the LHC in Run 2, it is
2315 particularly important to focus on resonant searches at high m_X . When conducting a search in the HH
2316 final state, the different possible decay modes of each Higgs must be considered. Figure 7.2 shows the
2317 branching ratio of the HH final state for different combinations of decays of each individual Higgs. As

²³¹⁸ the largest branching ratio for the 125 GeV Higgs is $H \rightarrow b\bar{b}$, the $HH \rightarrow b\bar{b}b\bar{b}$ branching ratio is also the
²³¹⁹ largest at 33%.

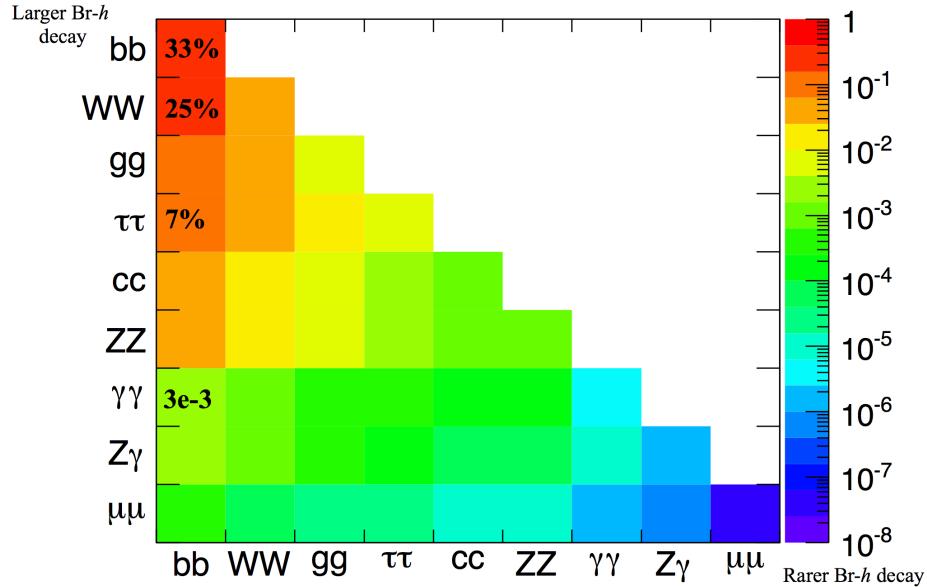

Figure 7.2: Summary of HH branching ratios [110].

²³²⁰ At high m_X , the Higgs bosons resulting from the decay of a heavy resonance will have large p_T ¹. The
²³²¹ angular separation between the decay products of the Higgs, $\Delta R \equiv \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$, is inversely
²³²² proportional to the Higgs p_T , as shown in equation 7.1.

$$\Delta R \approx \frac{2m}{p_T} \quad (7.1)$$

²³²³ Figure 7.3 shows the minimum ΔR between truth level B decay vertices in simulation samples for Randall-
²³²⁴ Sundrum gravitons of different masses. The figure shows that as the mass of the graviton increases, the ΔR
²³²⁵ distribution between the b quarks in the Higgs decay tends to shift to lower values. Because of this effect,
²³²⁶ it is necessary to tailor a selection to target these merged b -jets.

¹In the limit that the resonance mass is much larger than the Higgs mass, the Higgs p_T is roughly $m_X/2$.

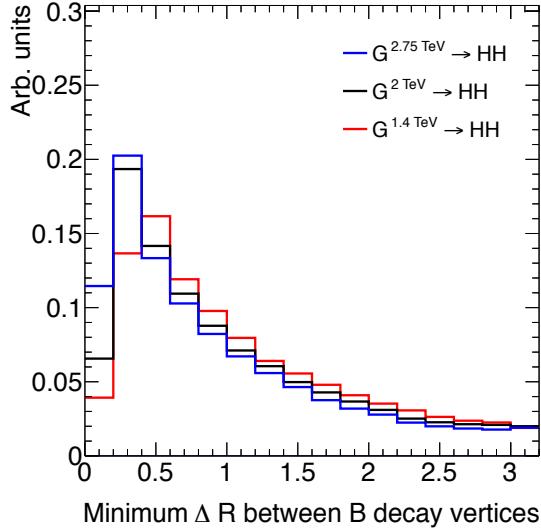

Figure 7.3: Minimum ΔR between B decay vertices for different RSG masses in a $G_{KK}^* \rightarrow HH \rightarrow 4b$ sample with $c = 1$.

2327 7.3 DATA AND SIMULATION SAMPLES

2328 7.3.1 SIGNAL MODELS

2329 While the resonance search is by its nature generic (as it is a simple search for a peak in the $4b$ invariant mass
 2330 spectrum), there are two signal models that the selection requirements have been optimized for. The first
 2331 is Randall-Sundrum (RSG) model, where a tower of massive spin-2 Kaluza-Klein gravitons is predicted.
 2332 The second is a heavy narrow scalar resonance, the so-called “heavy Higgs”. This type of resonance arises,
 2333 for example, in the two Higgs doublet model (2HDM). More details about the physics of these models
 2334 and their motivation is given in chapter 1.

2335 Signal graviton (G_{KK}^*) events are generated at leading order (LO) with **MADGRAPH5 v2.2.2** [ii]. The
 2336 PDF set used is the **NNPDF2.3 LO** set [ii]. For modeling parton shower and hadronization in jets, **PYTHIA**
 2337 8.186 is used with the A14 tune [90, ii]. The free parameters in the RSG model are the graviton mass
 2338 and the coupling constant $c \equiv k/\bar{M}_{\text{Pl}}^2$. Both the production cross section and width of the graviton are
 2339 proportional to c^2 . Samples are generated at both $c = 1$ and $c = 2$ for a variety of mass points between

² k is the curvature constant for the warped extra dimension and \bar{M}_{Pl} is the Planck mass divided by 8π

2340 300 GeV and 3 TeV.

2341 The second signal sample is a heavy spin-0 resonance H with a fixed width of $\Gamma_H = 1$ GeV. This
2342 is generated with **MADGRAPH5** and uses the **CT10** PDF set [93]. The parton shower and hadronization
2343 are handled by **HERWIG ++** with the **CTEQ6L1** PDF set and the **UEEE5** event tune [94, 114, 115]. Because
2344 the width and branching ratios depend on 2HDM parameters, each mass point generated with this fixed
2345 width corresponds to a different point in the 2HDM parameter phase space. Mass points are generated
2346 between 300 GeV and 1 TeV as with the RSG signal samples.

2347 7.3.2 BACKGROUND SAMPLES

2348 While the dominant **QCD** multijet background is estimated with a fully data-driven method, the sub-
2349 dominant backgrounds $t\bar{t}$ and Z +jets are modeled with some input from simulation.

2350 $t\bar{t}$ events are simulated at next-to-leading order (NLO) with the **POWHEG-BOX** version 1 generator us-
2351 ing the **CT10** PDF set [116]. The parton shower, hadronization, and underlying event are simulated with
2352 **PYTHIA 6.428** with the **CTEQ6L1** PDF set [89]. The Perugia 2012 tune is used [117]. NNLO **QCD** correc-
2353 tions to the cross sections are computed in **Top++ 2.0** [118]. The top quark mass is set to 172.5 GeV. The
2354 shapes of distributions in $t\bar{t}$ are taken from MC while the normalization is taken from data.

2355 Finally, the Z +jets background is simulated with **PYTHIA 8.186** and the **NNPDF2.3** LO PDF set. This
2356 background is negligible compared to the others and is taken fully from MC.

2357 7.3.3 DATA SAMPLE AND TRIGGER

2358 This analysis is done on 3.2 fb^{-1} of data taken in 2015 at $\sqrt{s} = 13$ TeV. The details of the machine
2359 conditions during this time can be found in Chapter 2. Only data which was taken during stable beam
2360 conditions with all detectors functioning is used. Events must pass a trigger which requires a single large
2361 radius ($R = 1.0$) jet with $p_T > 360$ GeV to be reconstructed in the HLT. Figure 7.4 shows the trigger
2362 efficiency for various trigger options as a function of graviton mass. Above $m_{G_{KK}^*} > 1$ TeV, the single
2363 large radius jet trigger is 99% efficient for events passing the signal selection.

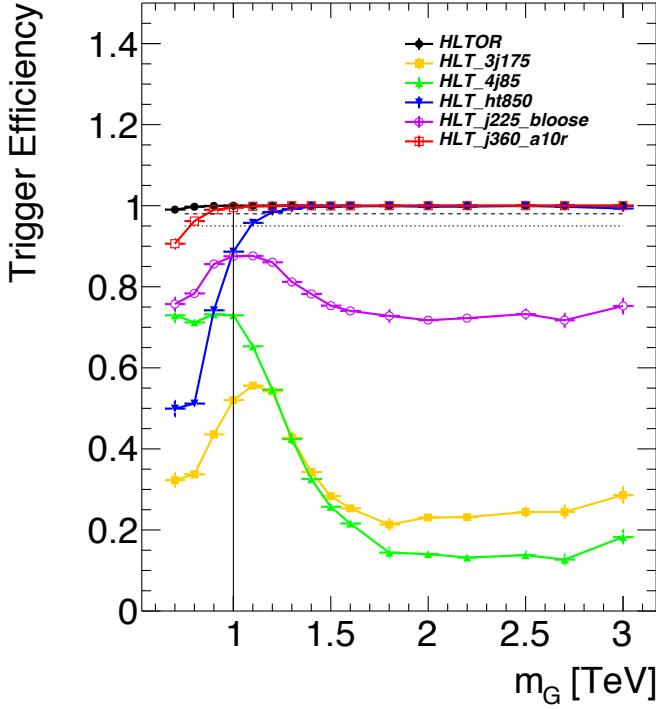

Figure 7.4: Trigger efficiency for events passing all signal region selections as a function of mass in $G_{KK}^* \rightarrow HH \rightarrow 4b$ samples with $c = 1$ [119]. In the trigger names, “j” refers to a jet or jets. “ht” refers to H_T , the scalar sum of transverse momenta in the event. “bloose” refers to a loose b -tagging requirement applied to the jet. “a10r” refers to anti- k_T jets with $R = 1.0$. The numbers at the end of each trigger name are the thresholds on the given quantity in GeV.

2364 7.4 EVENT RECONSTRUCTION AND OBJECT SELECTION

2365 The boosted selection first begins by defining a unique set of objects that can be exploited to increase signal
 2366 efficiency in the kinematic regime where the final state b -jets are very merged.

2367 7.4.1 LARGE RADIUS ($R = 1.0$) JETS

2368 The first step towards reconstructing the final state is to define objects that can be used to measure the
 2369 kinematics of the Higgs bosons. In the boosted selection anti- k_T jets with a radius parameter of 1.0 are
 2370 used. These jets are much larger in angular size than the typical $R = 0.4$ jets and are intended to encompass
 2371 all of the products of the Higgs decay³. The jets are built from clusters in the calorimeter calibrated with

³This is in contrast to the resolved selection, which uses two $R = 0.4$ anti- k_T jets for each Higgs.

local calibration weighting [69].

Because of the large extent of these jets, great care must be taken to remove potential contributions of calorimeter clusters from pile-up. This is done using a technique called jet trimming [120]. With trimming, the constituents of the large radius jet are re-clustered with a smaller radius using the k_T algorithm. Then, these so-called subjets are removed from the larger jet if $p_T^{\text{subjett}} / p_T^{\text{jet}} < f_{\text{cut}}$. In this analysis, the subjet radius is $R = 0.2$ and $f_{\text{cut}} = 0.05$. Trimming has been shown to improve the mass resolution of large radius jets. Figure 7.5 shows the effect of trimming on the large radius jet mass (M_J). Because the large radius jet fully contains the Higgs decay products, its invariant mass should correspond to the 125 GeV mass of the Higgs. The trimming algorithm brings the jet mass much closer to the expected Higgs mass and improves the mass resolution.

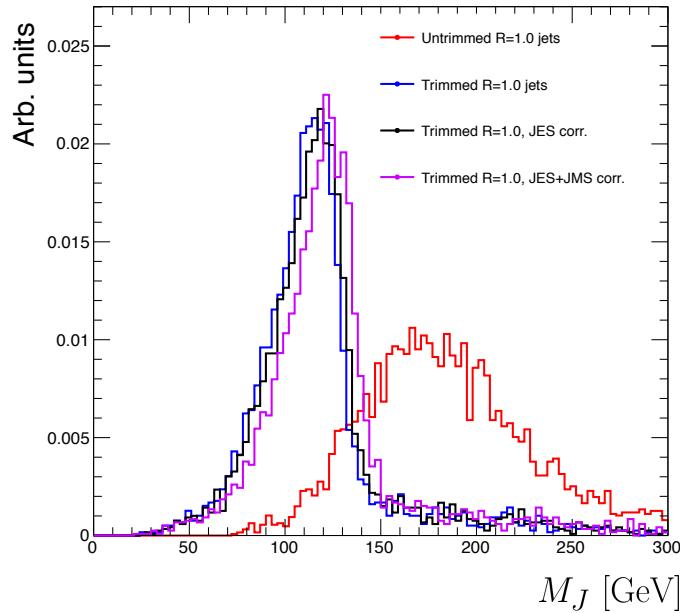

Figure 7.5: Comparison of untrimmed and trimmed jet masses for large radius jets in a RSG sample with $m_{G_{\text{KK}}^*} = 1 \text{ TeV}$. JES (JMS) refers to the standard jet energy (mass) scale calibration for ATLAS [69].

The large radius jets are required to satisfy $250 < p_T < 1500 \text{ GeV}$. They must also be within $|\eta| < 2.0$ in order to ensure that the full jet is within the inner detector tracking volume. Finally, they are required to have $M_J > 50 \text{ GeV}$. The upper p_T cut and lower threshold on mass are applied to correspond to the kinematic range where uncertainties are available in ATLAS calibrations [121, 122].

2386 7.4.2 TRACK JETS AND b -TAGGING

2387 Because the b -jets from boosted Higgs decays are so close together (as illustrated in figure 7.3), narrow radius
2388 jets are required to fully resolve both b -jets. The minimum radius feasible for jets based on calorimeter
2389 deposits is determined by the calorimeter granularity. However, because b -tagging relies on information
2390 from the inner detector, it is possible to define another type of jet that can have a smaller radius and better
2391 b -tagging resolution. These jets are called “track jets” [122, 123].

2392 Track jets are formed by applying the usual anti- k_T clustering algorithm to tracks that are required to be
2393 consistent with the primary vertex. After the jet axis has been determined using these tracks, a second step
2394 of track association is also performed to add tracks that can be useful for b -tagging [123]. In this analysis,
2395 the tracks are clustered with a radius parameter of $R = 0.2$. This radius has been shown to give good
2396 performance in boosted Higgs tagging [122, 123]. Figure 7.6 shows a comparison among different track jet
2397 radii of the efficiency for reconstructing two b -jets from each Higgs in a RSG sample as a function of mass.
Track jets with radius of 0.2 give the best performance, especially at high mass. In this analysis, track jets

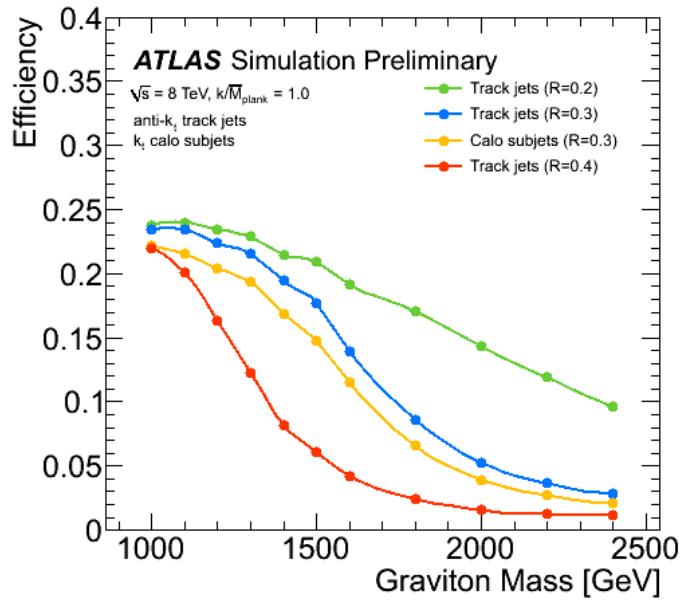

Figure 7.6: Efficiency of finding two b -jets from each Higgs in an RSG event using calorimeter jets with $R = 0.3$ and track jet radii of $R = [0.2, 0.3, 0.4]$ [123].

2398

2399 are required to have $p_T > 10$ GeV and $|\eta| < 2.5$. They must also have at least two tracks.

2400 7.4.3 MUONS

2401 Muons are used in this study to correct the four-momenta of calorimeter jets by accounting for semi-
2402 leptonic b decays. The muons used are combined ID and MS muons which must satisfy tight identification
2403 requirements [65]. The muons must have $p_T > 4 \text{ GeV}$ and $|\eta| < 2.5$. Table 7.1 summarizes the object
2404 requirements described in this section.

	R	p_T	$ \eta $	M
Calorimeter jets	1.0	$250 < p_T < 1500 \text{ GeV}$	< 2.0	$> 50 \text{ GeV}$
Track jets	0.2	$> 10 \text{ GeV}$	< 2.5	-
Muons	-	4 GeV	< 2.5	-

Table 7.1: Summary of requirements on objects used in the $X \rightarrow HH \rightarrow b\bar{b}b\bar{b}$ search

2405 7.5 EVENT SELECTION

2406 The first requirement in the boosted event selection is for ≥ 2 large radius jets satisfying the selections
2407 outlined above. The two highest momentum large-R jets in the event are referred to as “Higgs candidates”.
2408 The leading jet is required to have $p_T > 350 \text{ GeV}$.

2409 Track jets satisfying the object selections are matched to Higgs candidate jets via ghost association [124].
2410 Each Higgs candidate must have at least 2 track jets associated with it. These basic requirements are illus-
2411 trated graphically in figure 7.7.

2412 The QCD multijet background produces less central jets than high mass resonances, so there is an ad-
2413 dditional requirement that the two Higgs candidates be close together in η . The large-R jets are required to
2414 satisfy $|\Delta\eta(JJ)| < 1.7$.

2415 7.5.1 MASS REQUIREMENTS

2416 The final set of requirements ensures that the Higgs candidates are consistent with expected properties of
2417 the 125.0 GeV Higgs. First, a variable (X_{hh}) is defined to measure the consistency of both of the Higgs

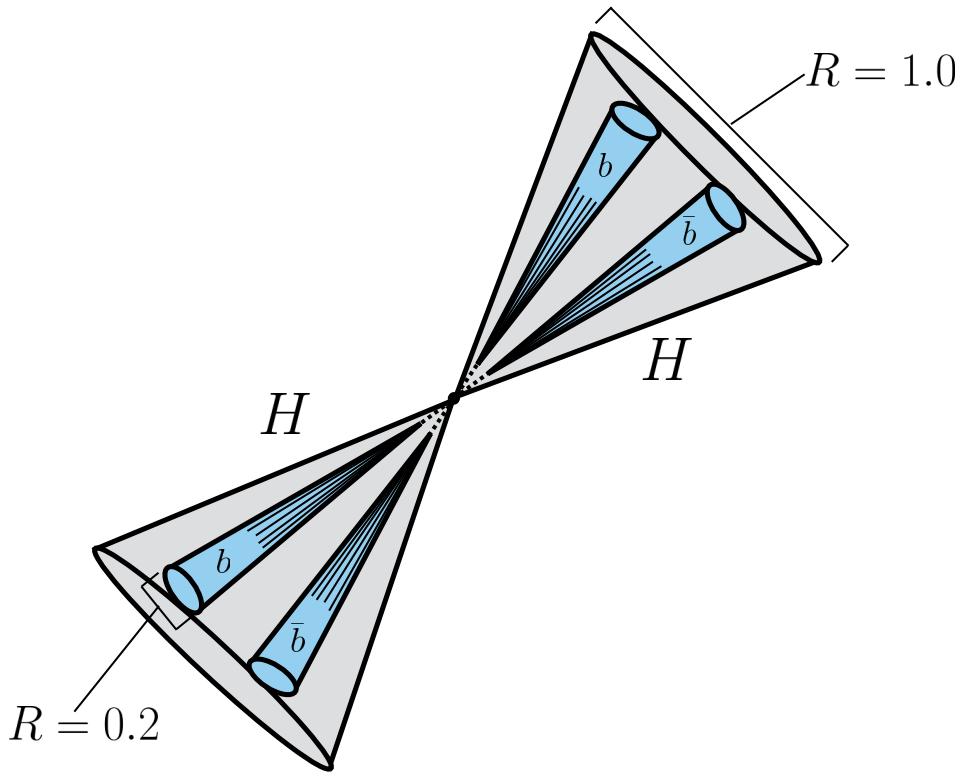

Figure 7.7: Illustration of the boosted selection requirements on Higgs candidates. Each large-radius calorimeter jet (Higgs candidate) must contain two track jets.

²⁴¹⁸ candidate jets with the SM Higgs mass. This is shown in equation 7.2.

$$X_{hh} = \sqrt{\left(\frac{M_J^{\text{lead}} - 124 \text{ GeV}}{0.1 M_J^{\text{lead}}}\right)^2 + \left(\frac{M_J^{\text{sublead}} - 115 \text{ GeV}}{0.1 M_J^{\text{sublead}}}\right)^2} \quad (7.2)$$

²⁴¹⁹ The mass values in the X_{hh} formula are optimized to maximize signal efficiency. The sub-leading jet typ-
²⁴²⁰ ically has a lower mass due to semi-leptonic b decays and final state radiation. X_{hh} effectively acts as a χ^2
²⁴²¹ measurement of the consistency of the two Higgs candidate masses with the signal hypothesis. The de-
²⁴²² nominators of each term ($0.1 M$) give the uncertainty on the mass measurement for the large radius jets.
²⁴²³ Events are required to satisfy $X_{hh} < 1.6$.

²⁴²⁴ Before making the requirement on X_{hh} , the masses of the Higgs candidates are corrected for semi-
²⁴²⁵ leptonic b decays using muons with the criteria outlined in the previous section. Any muons within a
²⁴²⁶ $\Delta R < 0.2$ of a b -tagged track jet (as described in the next section) have their four-momenta added to the

2427 four-momentum of the Higgs candidate. This correction does not affect the pre-selection requirements
 2428 but does affect the X_{hh} requirement and the final invariant mass discriminant.

2429 **7.5.2 b-TAGGING REQUIREMENTS**

2430 The last requirement applied is on the number of b -tagged track jets. There are two signal regions defined.
 2431 The first requires exactly four b -tagged track jets, two in each Higgs candidate (known as the $4b$ signal re-
 2432 gion). At high resonance masses, this requirement is inefficient, so an additional signal region requiring
 2433 only three b -tagged track jets is also defined (known as the $3b$ signal region). While this has a larger back-
 2434 ground it is also more efficient for high resonance masses. For both signal regions, the MV2c2o algorithm,
 2435 where the training sample for the algorithm has 20% charm events is used. More details for this algorithm
 2436 can be found in Chapter 2.

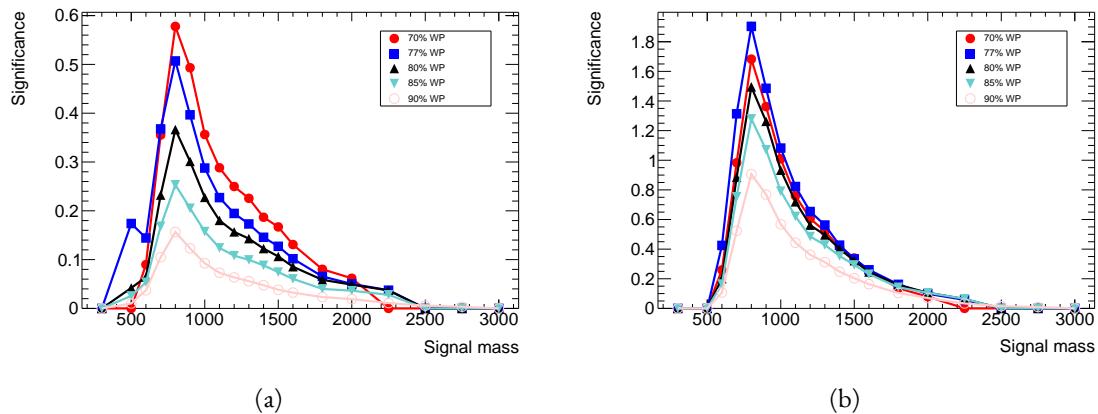

Figure 7.8: Estimated significance as a function of signal mass for RSG $c = 1$ models in the $3b$ (a) and $4b$ (b)
 regions for different b -tagging efficiency working points

2437 Once the algorithm is selected, an efficiency working point must also be chosen. This working point
 2438 defines the efficiency with which true b -jets are tagged and also fixes the overall background rejection of the
 2439 algorithm. Higher efficiency working points accept more true b -jets but also allow for more background.
 2440 Five different working points (70%, 77%, 80%, 85%, 90%) are tested. With each working point, the
 2441 full data driven background estimation method is run to quantify the amount of background that will be
 2442 present in the final signal region. The significance is quantified using the median discovery significance for

2443 signal and background with Poisson errors, given in equation 7.3 [125].

$$Z = \sqrt{2 \left((s + b) \ln \left(1 + \frac{s}{b} \right) - s \right)} \quad (7.3)$$

2444 Here, s is the expected number of signal events and b is the expected number of background events. This
 2445 formula is derived using Poisson statistics with errors on both the signal and background. It is used because
 2446 it is valid in the regime where s and b are of the same order. Note that in the limit where s is much smaller
 2447 than b , this equation reduces to the more well known s/\sqrt{b} . Figure 7.8 shows the estimated significance as
 2448 a function of signal mass in RSG $c = 1$ models for the $3b$ and $4b$ signal regions. The 77% working point
 2449 gives the best performance over a wide range of masses in the $4b$ signal region. As this is the region which
 2450 contributes the most to the total discovery significance, the 77% efficiency working point is chosen for the
 2451 analysis.

2452 7.5.3 SELECTION EFFICIENCY

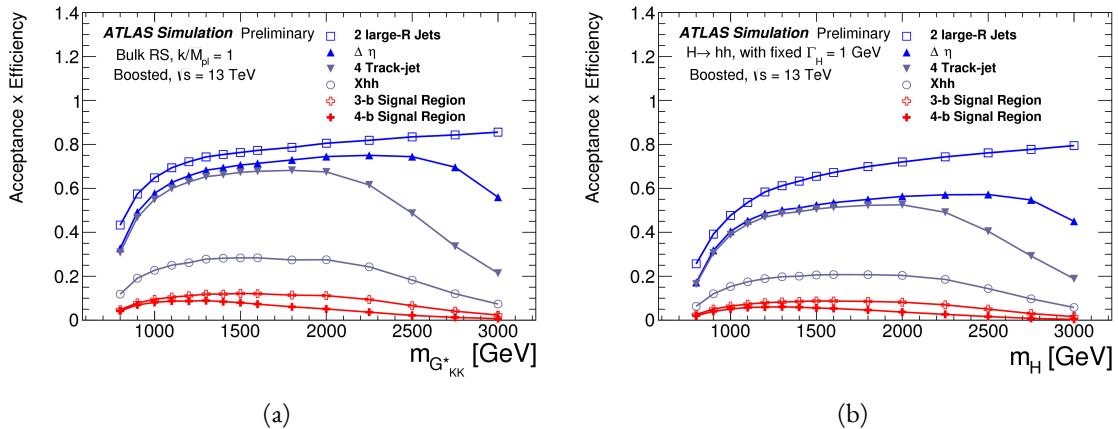

Figure 7.9: Acceptance \times efficiency as a function of mass for (a) RSG and (b) narrow heavy scalar signal models [126].

2453 Figure 7.9 shows the product of acceptance and efficiency as a function of mass for both the RSG and
 2454 narrow heavy scalar resonance signal models. After $m_X > 1$ TeV, the efficiency of the $4b$ requirement
 2455 begins to decline. After $m_X > 2$ TeV, the efficiency of requiring two track jets in each Higgs candidate
 2456 begins to decline as well. Both of these behaviors illustrate the difficulty of resolving the merged decay

products at high mass. Figure 7.10 shows a more detailed comparison of the signal efficiency in the $3b$ vs $4b$ signal regions for the RSG model. The efficiencies shown here are relative to all prior selection requirements. It can be seen there that at high masses the $3b$ signal region is more efficient for signal.

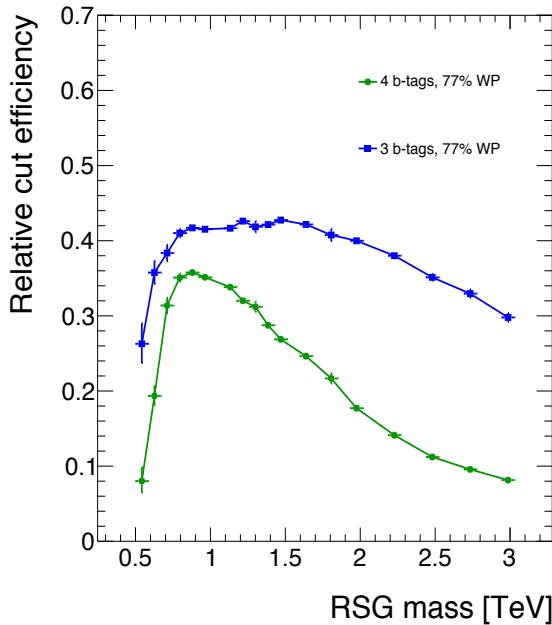

Figure 7.10: Efficiency of requiring 3 or 4 b -tagged track jets vs. RSG mass. The efficiency quoted is relative to the previous selection requirements (rather than an absolute efficiency).

To investigate the degradation of b -tagging efficiency at high p_T , the individual jet tagging efficiencies can be compared as a function of signal mass. This is shown in figure 7.11. The figure shows that the leading jet tagging efficiency in both calorimeter jets degrades heavily, while the sub-lead jet tagging efficiency remains relatively constant. More details on the cause of this degradation are shown in appendix A.

The final discriminating variable used in the boosted analysis is M_{2J} , the invariant mass of the two Higgs candidates. In order to improve the mass resolution, the four-momenta of each Higgs candidate are scaled by m_h/M_J . The effect of this correction is small in the boosted analysis but is done for consistency with the resolved selection. Table 7.2 shows the effect of the selection requirements on signal and background simulations as well as data.

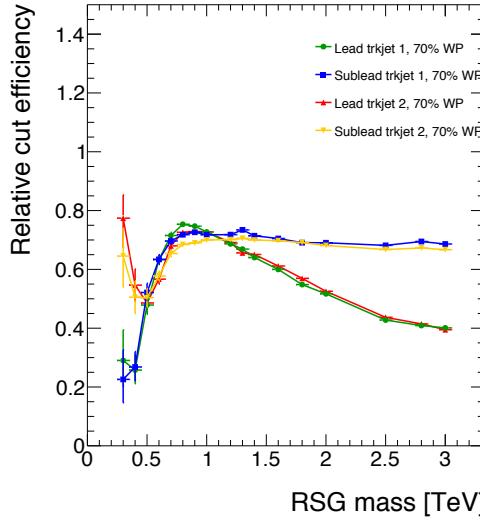

Figure 7.11: MV2c20 b -tagging efficiency for each of the four track jets in the boosted $4b$ selection as a function of RSG mass for $c = 1$ models.

Selection	Data	$m_{G_{KK}^*} = 1\text{TeV}$	$m_{G_{KK}^*} = 2\text{TeV}$	$t\bar{t}$	$Z + \text{jets}$
$N(\text{fiducial large-R jets}) \geq 2$	2202396	23.3	0.48	32345.2	4255.7
leading large-R jet $p_T > 350\text{ GeV}$	1873741	22.9	0.48	26511.7	3649.9
Both large-R jet $m > 50\text{ GeV}$	1854625	21.2	0.47	24369.8	3575.8
Both large-R jet $p_T < 1500\text{ GeV}$	1853601	21.2	0.46	24346.5	3572.9
$ \Delta\eta(JJ) < 1.7$	1435273	20.8	0.44	20751.0	3265.8
≥ 2 track-jets per large-R jet	1224727	19.8	0.40	18234.5	2692.6
3 b -tags, $X_{hh} < 1.6$	316	3.4	0.067	46.7	2.0
4 b -tags, $X_{hh} < 1.6$	20	2.9	0.030	1.4	0.0

Table 7.2: Effect of boosted selection on data, RSG signal models, $t\bar{t}$, and $Z + \text{jets}$. The numbers from simulation are normalized with the MC generator cross section and do not take into account the data driven estimates described in section 7.6 [127].

2469 7.6 DATA-DRIVEN BACKGROUND ESTIMATION

2470 The largest background to the $X \rightarrow HH \rightarrow b\bar{b}b\bar{b}$ final state is QCD multijet production, constitut-
 2471 ing 80-90% of the total background. Because of the difficulties in modeling higher order QCD processes,
 2472 this background is estimated with a fully data-driven method. The only other non-negligible background
 2473 is $t\bar{t}$, constituting the other 10-20%. Due to the presence of $t\bar{t}$ in the sideband region where the QCD

⁴The $Z + \text{jets}$ background is a sub-percent level contribution

2474 background will be estimated, the normalization of the QCD and $t\bar{t}$ backgrounds are simultaneously es-
2475 timated.

2476 7.6.1 MASS REGION DEFINITIONS

2477 The first step in the data-driven background estimate is to define a sideband mass region where the back-
2478 ground normalization can be derived. Additionally, a control region is defined where the background
2479 estimate can be validated. The control (CR) and sideband (SB) regions are defined using a radial distance
2480 in the two-dimensional large-R jet mass plane, R_{hh} , which is defined in equation 7.4.

$$R_{hh} = \sqrt{(M_J^{\text{lead}} - 124 \text{ GeV})^2 + (M_J^{\text{sublead}} - 115 \text{ GeV})^2} \quad (7.4)$$

2481 Events in the control region are required to fail the signal region $X_{hh} < 1.6$ requirement and have
2482 $R_{hh} < 35.8 \text{ GeV}$. The sideband region consists of those events which are not in the signal or control
regions. Figure 7.12 shows the definition of the signal, control, and sideband mass regions. Table 7.3 sum-

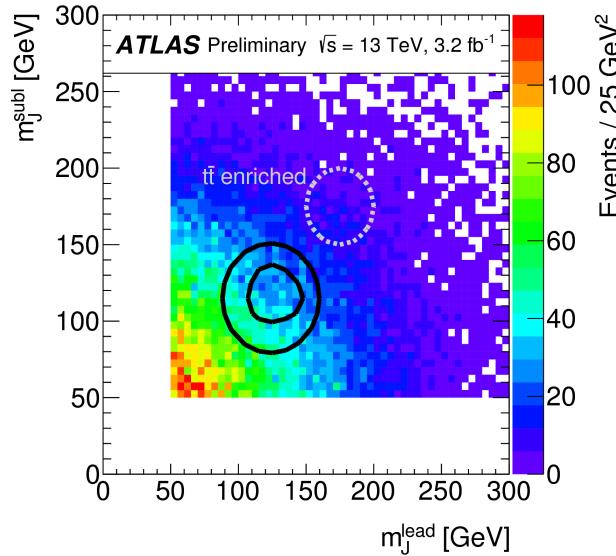

Figure 7.12: M_J^{sublead} vs. M_J^{lead} in a 2 b -tag data sample. The signal region is defined by the inner black contour ($X_{hh} < 1.6$) and the sideband region is defined by the outer contour ($R_{hh} > 35.8 \text{ GeV}$). The region between the black contours is the control region. The mass region which is enriched in $t\bar{t}$ background is also shown for illustration [[126](#)].

2483

2484 marizes the mass region selections for the three different regions used in the analysis.

Region	Requirement	Notes
Signal Region (SR)	$X_{hh} < 1.6$	-
Control Region (CR)	$R_{hh} < 35.8 \text{ GeV}$ and $X_{hh} > 1.6$	Used for validation of background estimates
Sideband Region (SB)	$R_{hh} > 35.8 \text{ GeV}$	Used to derive background normalization

Table 7.3: Mass region definitions used for background estimation.

2485 7.6.2 BACKGROUND ESTIMATION

2486 The method for estimating the background in this analysis is similar to the ABCD method presented in
 2487 Chapter 5. In this case, the two handles used to define different regions for the estimate are the number
 2488 of b -tagged track jets and the mass requirements. A region requiring exactly two b -tagged track jets in one
 2489 large-R jet (referred to as the 2-tag or $2b$ region) is defined for use in the background estimate. The number
 2490 of expected background events in the $3b$ and $4b$ signal regions is then given by equation 7.5.

$$N_{\text{bkg}}^{3(4)-\text{tag},\text{SR}} = \mu_{\text{Multijet}} N_{\text{Multijet}}^{2-\text{tag},\text{SR}} + \beta_{t\bar{t}} N_{t\bar{t}}^{3(4)-\text{tag},\text{SR}} + N_{Z+\text{jets}}^{3(4)-\text{tag},\text{SR}} \quad (7.5)$$

2491 In this equation, $N_{\text{bkg}}^{3(4)-\text{tag}}$ is the expected number of background events in the $3b$ or $4b$ signal regions.
 2492 $N_{\text{Multijet}}^{2-\text{tag}}$ is the number of multijet events in the 2-tag region. $N_{t\bar{t}}^{3(4)-\text{tag}}$ is the number of $t\bar{t}$ events pre-
 2493 dicted in the MC for the $3b$ or $4b$ signal region, and the variable is similarly defined for the $Z+\text{jets}$ back-
 2494 ground. The $\beta_{t\bar{t}}$ parameter is a scale factor used to correct the normalization of the $t\bar{t}$ estimate in the signal
 2495 region. μ_{Multijet} is an extrapolation factor that is derived in the sideband region and used to estimate the
 2496 ratio of 2-tag events to 3(4)-tag events in the signal region. It is defined in equation 7.6.

$$\mu_{\text{Multijet}} = \frac{N_{\text{Multijet}}^{3(4)-\text{tag},\text{SB}}}{N_{\text{Multijet}}^{2-\text{tag},\text{SB}}} = \frac{N_{\text{data}}^{3(4)-\text{tag},\text{SB}} - \beta_{t\bar{t}} N_{t\bar{t}}^{3(4)-\text{tag},\text{SB}} - N_{Z+\text{jets}}^{3(4)-\text{tag},\text{SB}}}{N_{\text{data}}^{2-\text{tag},\text{SB}} - \beta_{t\bar{t}} N_{t\bar{t}}^{2-\text{tag},\text{SB}} - N_{Z+\text{jets}}^{2-\text{tag},\text{SB}}} \quad (7.6)$$

2497 The $t\bar{t}$ scale factor ($\beta_{t\bar{t}}$) and the QCD multijet extrapolation factor (μ_{Multijet}) are estimated together in
 2498 a simultaneous fit in the sideband region. Then, the number of events in the 2-tag signal region is used,
 2499 along with the $t\bar{t}$ estimate in the $3b$ and $4b$ signal regions and μ_{Multijet} , to estimate the total number
 2500 of background events in the two final signal regions. The shape of the final discriminant M_{2J} is also

2501 taken from the 2-tag signal region where there are more events. This method is illustrated graphically in
2502 figure 7.13. In the $3b$ region, the fit yields values of $\mu_{\text{Multijet}} = 0.160 \pm 0.03$ and $\beta_{t\bar{t}} = 1.02 \pm 0.09$.

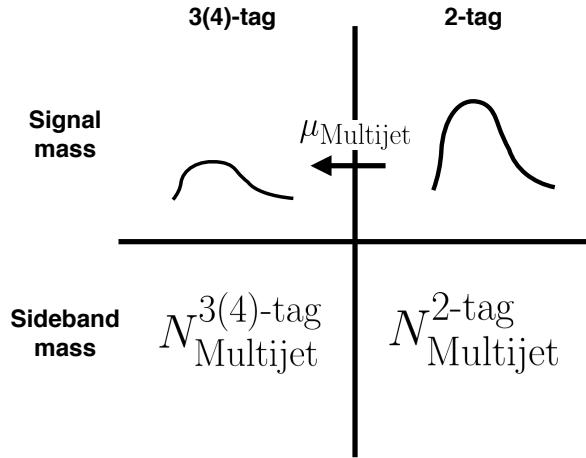

Figure 7.13: An illustration of the data-driven background estimation technique for the boosted analysis

2503 In the $4b$ region, the fit gives $\mu_{\text{Multijet}} = 0.0091 \pm 0.0007$ and $\beta_{t\bar{t}} = 0.82 \pm 0.39$. The uncertainties
2504 quoted are statistical only. The larger uncertainties in the $4b$ values indicate the lower statistics available in
2505 that region.

2506 Figure 7.14 shows the distributions of data and background estimates in the $3b$ and $4b$ sideband regions
2507 after the background fit has been done. The normalizations are constrained from the fit to match that of
2508 the data, but good modeling of the shape of the mass of the leading large-R jet is seen as well. The shapes
2509 of the kinematic distributions for the $t\bar{t}$ background in the $4b$ region are taken from the $3b$ region due to
2510 the better MC statistics in that region.

2511 7.6.3 BACKGROUND SHAPE FIT

2512 As mentioned in the previous section, the background shape in the 3-tag and 4-tag signal regions is taken
2513 from the 2-tag signal mass region. Due to the limited statistics available, the background shapes are addi-
2514 tionally smoothed after being extrapolated to the 3-tag and 4-tag signal regions. Only the data in the range
2515 $900 < M_{2J} < 2000$ GeV is included in the shape fit due to the limited statistics available above 2 TeV.
2516 Both the $t\bar{t}$ and QCD multijet background are independently fit with an exponential shape, $y = e^{ax+b}$.

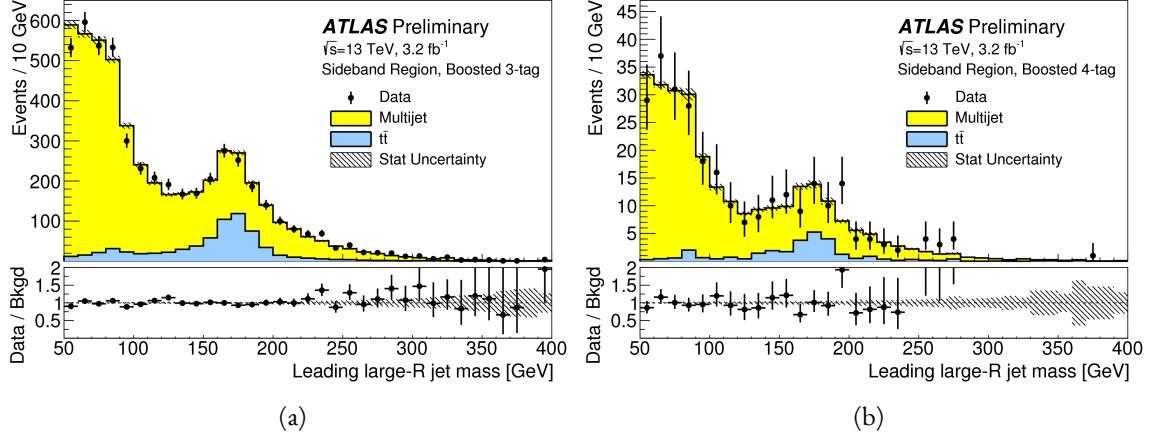

Figure 7.14: Leading large-R jet mass in the 3b (a) and 4b (b) sideband regions. The multijet and $t\bar{t}$ backgrounds are estimated using the data-driven methods described above. Because their normalizations are derived in the sideband region, the total background normalization is constrained by default to match the normalization of the data [126].

2517 Other shapes are considered and used for the systematic uncertainties. Table 7.4 shows the fit values for
 2518 the parameters. Because both the 3b and 4b QCD shapes come from the 2-tag region, the slopes derived
 2519 are very similar.

	a	b
QCD (4b)	0.00545 ± 0.00021	5.44 ± 0.24
$t\bar{t}$ (4b)	0.00746 ± 0.00021	4.88 ± 0.36
QCD (3b)	0.00545 ± 0.00021	8.30 ± 0.24
$t\bar{t}$ (3b)	0.00746 ± 0.00021	8.58 ± 0.36

Table 7.4: Parameters derived for exponential fit to background M_{2J} shape in the 3b and 4b signal regions [127].

2520 7.6.4 VALIDATION OF BACKGROUND ESTIMATE

2521 The background estimate can be validated by using the method to estimate the number of events in the
 2522 control mass region rather than the signal mass region. Figure 7.15 shows the M_{2J} distribution in the 3b
 2523 and 4b control regions, comparing data and background estimates. In both cases, both the background
 2524 shape and normalization are consistent with the data, indicating good agreement. The ratio of data to the
 2525 background estimates is also fit to a line in the figure to test for any shape difference. The slope of the
 2526 line is within 1σ (from the fit uncertainties) of flat, further indicating that the data is consistent with the
 2527 background estimate in the control region.

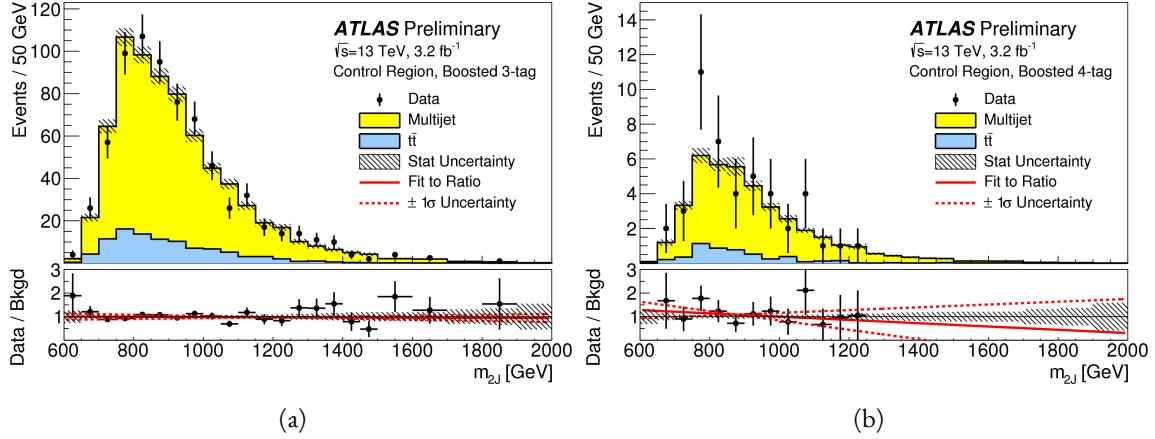

Figure 7.15: Di-jet invariant mass (M_{2J}) in the 3b (a) and 4b (b) control regions. The multijet and $t\bar{t}$ backgrounds are estimated using the data-driven methods described above [126].

Table 7.5 shows the yields in data and background estimates in the 3-tag and 4-tag sideband and control regions. Again, here, it can be seen that the total number of predicted background events from the data driven method is consistent with the number of data events in the region.

Sample (3-tag)	Sideband Region	Control Region
Multijet	4328 ± 27	607 ± 10
$t\bar{t}$	683.5 ± 8.1	99.6 ± 3.1
Z+jets	31.8 ± 3.7	7.7 ± 1.8
Total	5043 ± 28	715 ± 11
Data	5043	724
Sample (4-tag)	Sideband Region	Control Region
Multijet	247.4 ± 1.5	34.7 ± 0.6
$t\bar{t}$	28.4 ± 1.5	5.1 ± 0.7
Z+jets	3.4 ± 1.2	0.6 ± 0.5
Total	279.2 ± 2.5	40.3 ± 1.0
Data	279	45

Table 7.5: The number of events in data and predicted background events in the boosted 3-tag and 4-tag sideband and control regions [126]. The uncertainties shown are statistical only.

2531 7.7 SYSTEMATIC UNCERTAINTIES

2532 The systematic uncertainties in this analysis can be divided into two broad categories. The first type is
2533 uncertainties associated with the modeling of the signal processes. The second type of uncertainty is asso-
2534 ciated with both the shape and normalization of the background prediction.

2535 7.7.1 SIGNAL MODELING UNCERTAINTIES

2536 The signal modeling uncertainty has three main components: theoretical uncertainty on the acceptance,
2537 experimental uncertainties on the large-R jets, and experimental uncertainties on the track jets related to
2538 b -tagging. In this analysis the experimental uncertainties are the most significant.

2539 The first uncertainty on signal modeling is the theoretical uncertainty on the acceptance. As explained
2540 in section 5.6.1, there are four components to this uncertainty. The first is related to missing higher order
2541 terms from the matrix element calculations which is estimated by varying the QCD renormalization and
2542 factorization scales. The second is uncertainty due to the PDF set used. The third is a generator uncer-
2543 tainty which is estimated by modifying the generator used to model the underlying event and hadroniza-
2544 tion. Finally, there is an uncertainty associated with the modeling of the initial state and final state radia-
2545 tion (ISR/FSR). The total theoretical uncertainty on the signal yield is 3%, and this is dominated by the
2546 ISR/FSR modeling.

2547 There are uncertainties on the large-R jets in both the jet energy scale (JES) and jet energy resolution
2548 (JER) as well as the jet mass scale (JMS) and jet mass resolution (JMR). These are evaluated using $\sqrt{s} =$
2549 8 TeV data from Run 1 of ATLAS and extrapolated to the Run 2 beam and detector conditions using
2550 MC⁵. The details of these uncertainties can be found in reference [128].

2551 Uncertainties on the track jets are related to the b -tagging efficiency. The total uncertainty on the signal
2552 yield due to b -tagging is evaluated by propagating variations of the b -tagging efficiency through the boosted
2553 selection requirements. The uncertainties are calculated jet-by-jet and parameterized as a function of b -jet
2554 p_T and η [106]. For high p_T b -jets (with $p_T > 300$ GeV), the uncertainties are extrapolated using MC
2555 simulation from the lower p_T b -jets [129].

⁵The uncertainties are correspondingly larger due to the uncertainty of this extrapolation.

2556 Table 7.6 shows the systematic uncertainties on the signal normalization for models with $m_{G_{\text{KK}}^*} =$
 2557 1.5 TeV and both $c = 1$ and $c = 2$ as well as a narrow width heavy scalar. The dominant uncertainty
 2558 comes from b -tagging and this uncertainty is larger in the 4-tag region than the 3-tag region.

Source	Background		G_{KK}^*	H

Table 7.6: Summary of systematic uncertainties in the total background and signal event yields (expressed in %) in the boosted 3-tag and 4-tag signal regions. Systematic uncertainties on the signal normalization are shown for models with $m_{G_{\text{KK}}^*} = 1.5 \text{ TeV}$ and both $c = 1$ and $c = 2$ as well as a narrow width heavy scalar.

2559 **7.7.2 BACKGROUND UNCERTAINTIES**

2560 Uncertainties on the QCD multijet background normalization and shape are estimated using the con-
 2561 trol mass region. As shown previously, the background predictions in the control region match with the

2562 data yields within the statistical uncertainty in both the 3-tag and 4-tag control regions. As an additional
 2563 protection, the statistical uncertainty on the background prediction in the control region is assigned as a
 2564 systematic uncertainty on the normalization of the QCD background.

2565 Additional robustness tests are done by varying the definition of the control mass region and the b -
 2566 tagging requirements used to define the 2-tag sample. In all cases, the effect of the variations is found to be
 2567 within the statistical uncertainties on the background normalization in the control region.

2568 Shape uncertainties on the background are evaluated using two techniques. First, as shown in fig-
 2569 ure 7.15, the ratio between the data and background prediction is fit with a linear function. The uncer-
 2570 tainties on the slope of this fit are assigned as shape uncertainties. An additional uncertainty is assigned by
 2571 using alternate power law fit functions for the smoothing of the background shape. Table 7.7 shows the
 2572 alternate shapes used. The largest difference between the nominal fit function and the alternates, taking
 2573 into account the 1σ uncertainty band on each fit as well, is taken as a shape uncertainty.

Functional Form
$f_1(x) = p_0(1 - x)^{p_1}x^{p_2}$
$f_2(x) = p_0(1 - x)^{p_1}e^{p_2 x^2}$
$f_3(x) = p_0(1 - x)^{p_1}x^{p_2}x$
$f_4(x) = p_0(1 - x)^{p_1}x^{p_2} \ln x$
$f_5(x) = p_0(1 - x)^{p_1}(1 + x)^{p_2}x$
$f_6(x) = p_0(1 - x)^{p_1}(1 + x)^{p_2} \ln x$
$f_7(x) = \frac{p_0}{x}(1 - x)^{p_1-p_2} \ln x$
$f_8(x) = \frac{p_0}{x^2}(1 - x)^{p_1-p_2} \ln x$

Table 7.7: Alternate fit functions used to model the M_{2J} distribution in the QCD multijet background. In the equations, $x = M_{2J}/\sqrt{s}$.

2574 The uncertainties on the $t\bar{t}$ background are obtained by propagating the various experimental variations
 2575 (JES, JER, JMS, JMR, b -tagging) through the analysis selection requirements. Table 7.6 summarizes the
 2576 background uncertainties in the 3-tag and 4-tag regions.

2577 **7.8 RESULTS**

2578 Table 7.8 shows the observed yields in the 3-tag and 4-tag signal regions for the boosted analysis compared
2579 to the predicted number of background events. In the 3-tag region, 316 events are observed with a pre-
2580 dicted background of 285 ± 19 . In the 4-tag region, 20 events are observed with a predicted background
2581 of 14.6 ± 2.4 . Figure 7.16 shows the M_{2J} distribution in the 3-tag and 4-tag regions. There are some
2582 small excesses in the data, in particular in the 3-tag region around $M_{2J} \approx 900$ GeV and in the region of
2583 $1.6 < M_{2J} < 2.0$ TeV. The significance of these excesses will be evaluated in the next chapter in the
2584 statistical combination with the resolved results.

Sample	Signal Region (3-tag)	Signal Region (4-tag)
Multijet	235 ± 14	13.5 ± 2.4
$t\bar{t}$	48 ± 22	1.2 ± 1.0
$Z + \text{jets}$	2.0 ± 2.2	-
Total	285 ± 19	14.6 ± 2.4
Data	316	20
G_{KK}^* (1000 GeV), $c = 1$	3.4 ± 0.9	2.9 ± 1.1

Table 7.8: Observed yields in the 3-tag and 4-tag signal regions for the boosted analysis compared to the predicted number of background events Errors correspond to the total uncertainties in the predicted event yields. The yields for a graviton with $m_{G_{\text{KK}}^*} = 1$ TeV and $c = 1$ are also shown [126].

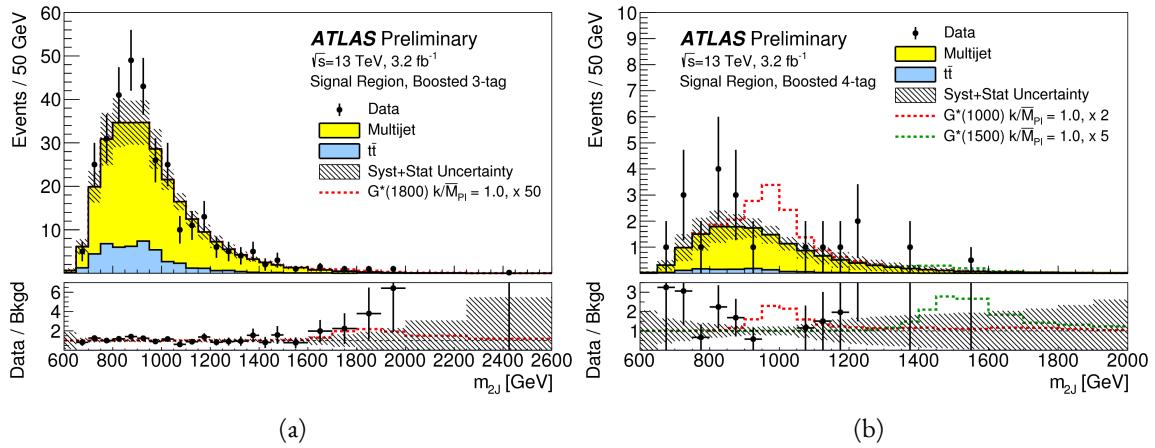

Figure 7.16: Di-jet invariant mass (M_{2J}) in the $3b$ (a) and $4b$ (b) signal regions. The multijet and $t\bar{t}$ backgrounds are estimated using the data-driven methods described above. In the $3b$ region, a graviton signal with $m_{G_{KK}^*} = 1.8$ TeV and $c = 1$ is overlaid, with the cross section multiplied by a factor of 50 so that the signal is visible. In the $4b$ region, signals with $m_{G_{KK}^*} = 1.0$ TeV and $m_{G_{KK}^*} = 1.5$ TeV are overlaid, both with $c = 1$ and the yields multiplied by factors of 2 and 5 respectively [126].

*There is no real ending. It's just the place where you stop
the story.*

2586

Combined limits from boosted and resolved searches

2587

2588

8.1 INTRODUCTION

2589 In order to cover the full mass range of possible resonances decaying to di-Higgs final states, two distinct
2590 tailored selections were produced. The resolved selection is more sensitive in the mass range of $400 < m_X < 1100$ GeV while the boosted selection is more sensitive to masses in the range $1100 < m_X <$
2591 3000 GeV. Chapter 7 presents the details of the boosted selection and results. In setting limits on spin-2
2592 Randall-Sundrum graviton (RSG) and narrow width heavy scalar (H) models, the results of the boosted
2593 selection are combined with the results of the resolved selection to cover the full mass range.
2594

2595 This chapter presents limits on signal models resulting from the $X \rightarrow HH \rightarrow b\bar{b}b\bar{b}$ search in both
2596 the resolved and boosted selections. It first presents a brief overview of the resolved results that go into

2597 the limit setting. Then, an overview of the statistical methods used for the search and limit setting is given.
2598 Finally, limits on the RSG and heavy scalar models are presented.

2599 **8.2 RESOLVED RESULTS**

2600 The details of the resolved selection will not be presented here and can be found in reference [126]. In
2601 basic terms, the selection searches for four $R = 0.4$ b-tagged calorimeter jets (where each pair of jets is
2602 one Higgs candidate). This is distinct from the boosted methodology which searches for merged decay
2603 products. The backgrounds to the resolved selection are the same as those presented in Chapter 7 for the
2604 boosted analysis.

2605 Table 8.1 shows the results for data yields and expected background in the resolved signal region. Fig-
2606 ure 8.1 shows the M_{2J} distribution in the resolved signal region. The total number of events is consistent
2607 with the prediction and no significant excess is seen. One event in the boosted 4-tag signal is shared with
2608 the resolved signal region and has a mass of 852 GeV.

Sample	Signal Region Yield
Multijet	43.3 ± 2.3
$t\bar{t}$	4.3 ± 3.0
$Z + \text{jets}$	-
Total	47.6 ± 3.8
Data	46
SM hh	0.25 ± 0.07
$G_{\text{KK}}^*(800 \text{ GeV}), c = 1$	5.7 ± 1.5

Table 8.1: Observed yields in the resolved selection 4-tag signal region compared to the predicted number of background events Errors correspond to the total uncertainties in the predicted event yields. The yields for a graviton with $m_{G_{\text{KK}}^*} = 800$ GeV and $c = 1$ are also shown [126].

2609 **8.3 SEARCH TECHNIQUE AND RESULTS**

2610 The statistical technique used for the search in this analysis is the same as that used in the $H \rightarrow WW^*$
2611 analysis presented in section 3.6.2. The test statistic q_0 is used to define the p -values which measure the

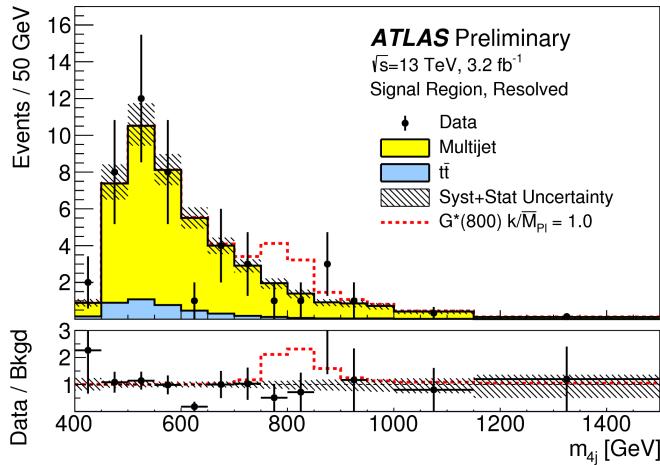

Figure 8.1: Di-jet invariant mass (M_{2J}) in the resolved signal region. A graviton signal with $m_{G_{KK}^*} = 800 \text{ GeV}$ and $c = 1$ is overlaid. [126].

compatibility of the data with the background-only hypothesis corresponding to a signal strength $\mu = 0$.

Local p_0 values are computed to quantify the probability that the background could produce a fluctuation greater than or equal to the one observed in the data. In the resolved analysis, no significant excesses are observed. The largest discrepancy with respect to the background only hypothesis occurs near a resonance mass of 900 GeV and is found to be less than 2σ in significance.

In the boosted selection, the largest local excess is a broad excess in the $3b$ signal region that begins near $M_{2J} \approx 1.7 \text{ GeV}$. Assuming a G_{KK}^* with this mass and $c = 1.0$, the local significance of this excess is 2.0σ .

8.4 LIMIT SETTING

In the absence of any significant excess observed in the data, limits on different signal models can be set. This section describes the limit setting procedure and presents combined results of the resolved and boosted analyses.

8.4.1 LIMIT SETTING PROCEDURE

The procedure used for setting exclusion limits in this analysis is the CL_s method [130]. The first step in setting the limits is to define a test statistic which will be used. For limit setting, the test statistic is shown

2627 in equation 8.1.

$$\widetilde{q}_\mu = \begin{cases} -2 \ln \frac{L(\mu, \hat{\theta}(\mu))}{L(0, \hat{\theta}(0))} & \hat{\mu} < 0 \\ -2 \ln \frac{L(\mu, \hat{\theta}(\mu))}{L(\hat{\mu}, \hat{\theta})} & 0 \leq \hat{\mu} < \mu \\ 0 & \hat{\mu} > \mu \end{cases} \quad (8.1)$$

2628 In the above equation, μ is the value of the signal strength under test, $\hat{\mu}$ is the best fit μ , $\hat{\theta}$ is the best fit
2629 value of the nuisance parameters, $\hat{\theta}$ is the best fit value of the nuisance parameters under the fixed μ value,
2630 and L is the Poisson likelihood of the data (as described in section 3.6.2).

2631 The test statistic \widetilde{q}_μ is constructed to protect against two interesting corner cases when setting the upper
2632 limit on the cross section. First, it protects against negative signal strengths μ which are unphysical. Second,
2633 it does not count excesses in the data larger than those expected by a signal strength μ as evidence against
2634 the μ hypothesis.

2635 The CL_s statistic is constructed by taking a ratio of two probabilities. CL_{s+b} is the probability that the
2636 signal+background hypothesis would produce a value of the test statistic that is less than or equal to the
2637 observed value¹. CL_b is the probability that the background only hypothesis will produce a value
2638 of the test statistic less than or equal to the observed. The CL_s statistic is the ratio CL_{s+b}/CL_b . A 95%
2639 upper limit on the cross section is set at the value of μ that makes the CL_s statistic less than 5%. In practice,
2640 the limits are computed numerically within an asymptotic approximation for the distribution of the test
2641 statistic \widetilde{q}_μ . The details of this approximation can be found in reference [76].

2642 The resolved and boosted analyses are combined using a very simple procedure rather than a full statis-
2643 tical combination. For each mass point tested, the limit which gives the most stringent constraint is used.
2644 This means that for mass points below 1.1 TeV the resolved signal region is used, while at and above this
2645 point the combination of the orthogonal 3b and 4b boosted signal regions is used.

2646 8.4.2 LIMIT SETTING RESULTS

2647 Figure 8.2 shows the combined 95% upper bounds as a function of mass for three different models: G_{KK}^*
2648 with $c = 1$, G_{KK}^* with $c = 2$, and a narrow heavy scalar H .

¹Lower values of \widetilde{q}_μ mean better compatibility.

2649 The cross section of $\sigma(pp \rightarrow G_{KK}^* \rightarrow hh \rightarrow b\bar{b}b\bar{b})$ with $c = 1$ is constrained to be less than 70 fb
2650 for masses in the range $600 < m_{G_{KK}^*} < 3000$ GeV. For the RSG model with $c = 2$, cross sections limits
2651 between 40 fb and 200 fb are set for the mass range of $500 < m_{G_{KK}^*} < 3000$ GeV. Masses in the range
2652 of $475 < m_{G_{KK}^*} < 785$ GeV are excluded with $c = 1$ (with an exclusion of the range 465 to 745 GeV
2653 expected). Masses less than 980 GeV are excluded with $c = 2$ (with an exclusion for masses less than
2654 1 TeV expected).

2655 In the heavy Higgs model, the cross section upper limits for $\sigma(pp \rightarrow H \rightarrow hh \rightarrow b\bar{b}b\bar{b})$ ranges from
2656 30 to 300 fb in the mass range of $500 < m_H < 3000$ GeV. The resolved analysis can also set an upper
2657 limit on the Standard Model di-Higgs production cross section discussed in chapter 3. The upper limit on
2658 $\sigma(pp \rightarrow hh \rightarrow b\bar{b}b\bar{b})$ in the Standard Model is constrained to be less than 1.22 pb.

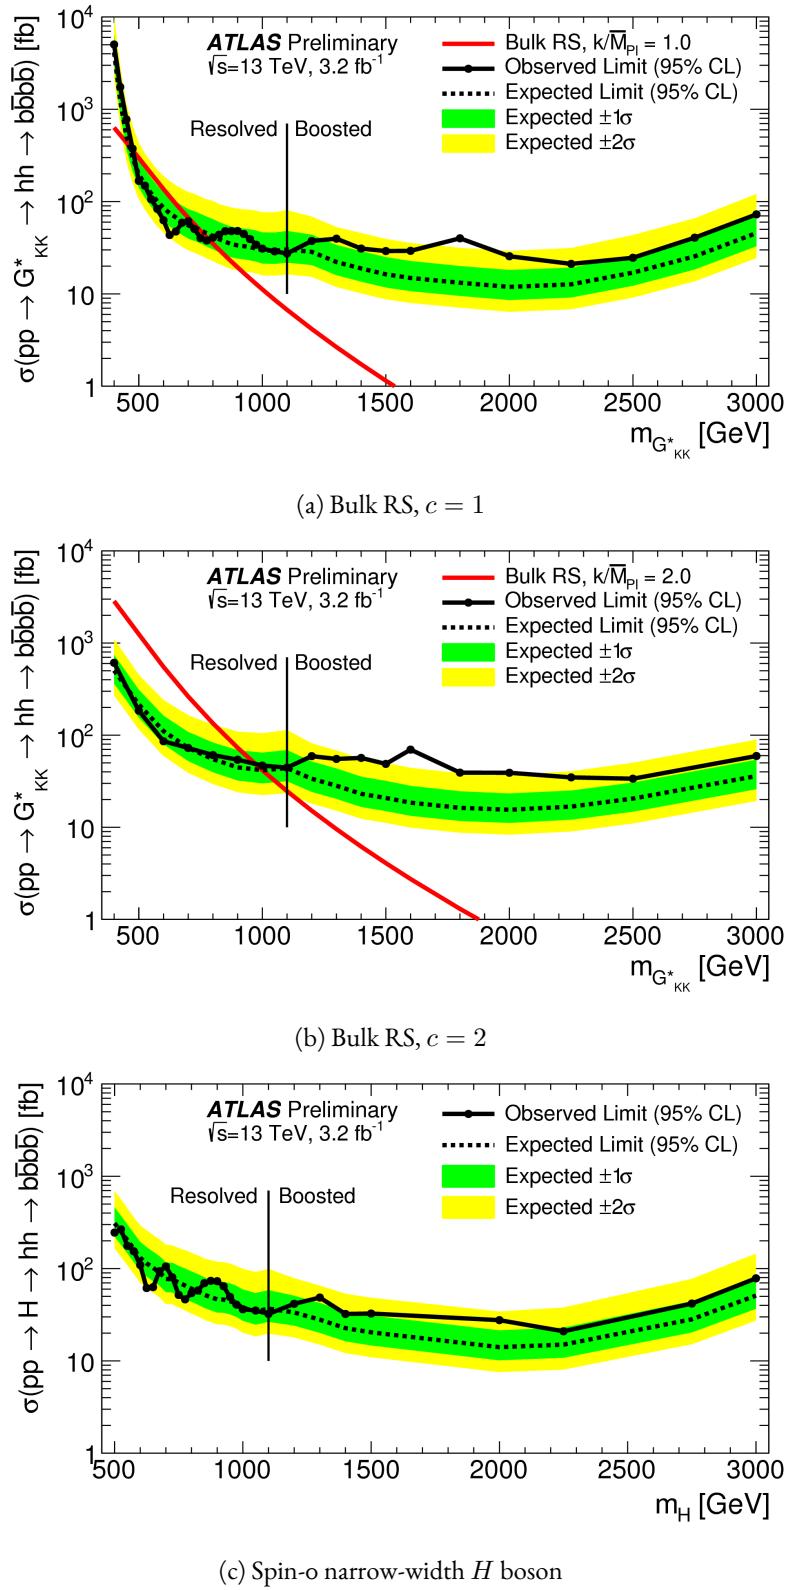

Figure 8.2: Expected and observed upper limit as a function of mass for G^*_{KK} in the RSG model with (a) $c = 1$ and (b) $c = 2$, as well as (c) H with fixed $\Gamma_H = 1$ GeV, at the 95% confidence level in the CL_s method [126].

2661

Conclusion

2662

2663 After being sought for many years at different collider experiments, the Higgs boson was discovered by
2664 the ATLAS and CMS experiments in 2012, confirming the leading theory for the source of electroweak
2665 symmetry breaking and filling in the last missing piece of the Standard Model. After its discovery, mea-
2666 surements of the particle's detailed properties and searches for new particles decaying to Higgs final states
2667 were both extremely important in constraining physics beyond the Standard Model. This dissertation
2668 presented this evolution through two results: the observation and measurement of the Higgs boson in the
2669 $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ channel at $\sqrt{s} = 7$ TeV and $\sqrt{s} = 8$ TeV and a search for Higgs pair production
2670 in the $HH \rightarrow b\bar{b}b\bar{b}$ channel at $\sqrt{s} = 13$ TeV with the ATLAS detector in pp collisions at the Large
2671 Hadron Collider.

2672 In the $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$, results from both the discovery of the Higgs boson and the full ATLAS
2673 Run 1 dataset were presented. The Higgs boson was discovered with a 5.9σ significance in a combination
2674 of the $H \rightarrow \gamma\gamma$, $H \rightarrow ZZ \rightarrow 4\ell$, $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ with 4.2 fb^{-1} at $\sqrt{s} = 7$ TeV and 5.2 fb^{-1} at

2675 $\sqrt{s} = 8$ TeV. With the full 20.3 fb^{-1} at $\sqrt{s} = 8$ TeV and 4.2 fb^{-1} at $\sqrt{s} = 7$ TeV, ATLAS achieved dis-
2676covery level significance in the $H \rightarrow WW^*$ channel alone and obtained the first evidence of vector boson
2677fusion production in that channel. The combined signal strength was measured to be $\mu = 1.09^{+0.23}_{-0.21}$. The
2678total observed significance of the $H \rightarrow WW^*$ process was observed to be 6.1σ (with 5.8σ expected). Ad-
2679vanced methods for background reduction and estimation, particularly in same-flavor lepton final states,
2680were shown. The VBF signal strength was measured to be $\mu_{\text{VBF}} = 1.27^{+0.53}_{-0.45}$ with an observed signifi-
2681cance of 3.2σ (with 2.7σ expected).

2682 These results required many novel innovations. The increase of pileup interactions in the higher in-
2683stantaneous luminosity LHC conditions of 2012 led to a degradation of missing transverse momentum
2684resolution. As a result, the prominent $Z/\gamma^* + \text{jets}$ background of the same flavor $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$
2685final states increased greatly. New variables, including a track-based missing transverse momentum and a
2686measurement of the balance between the dilepton system and recoiling jets, allowed for significant reduc-
2687tion of this background. In the VBF channel, selections were optimized to exploit the unique VBF final
2688state topology. Incorporating these variables into a boosted decision tree technique allowed the analysis
2689to exceed the 3σ statistical significance threshold.

2690 After the end of Run 1, the results of Higgs measurements from ATLAS were combined with those
2691from CMS to produce the most precise measurements of the Higgs boson so far [131]. Figure 9.1 shows the
2692combination of ATLAS and CMS data for the Higgs signal strength in and coupling measurements. In the
2693signal strength measurements of gluon fusion and vector boson fusion, the $H \rightarrow WW^*$ channel provides
2694the tightest constraints. Additionally, the Higgs coupling to W bosons is the most precisely measured with
2695a relative uncertainty of 10%.

2696 With the discovery of the Higgs firmly established and its properties measured, a natural next step was
2697to search for new physics with Higgs final states. At $\sqrt{s} = 13$ TeV, a search for Higgs pair production
2698in the $b\bar{b}b\bar{b}$ final state with 3.2 fb^{-1} was conducted. A signal region optimized for the boosted final states
2699arising from high mass resonances was constructed. This signal region utilized large-radius calorimeter jets
2700and b -tagging with small radius track jets to maximize the signal acceptance. No significant excesses were
2701observed, and upper limits on cross sections are placed for spin-2 Randall Sundrum gravitons (RSG) and

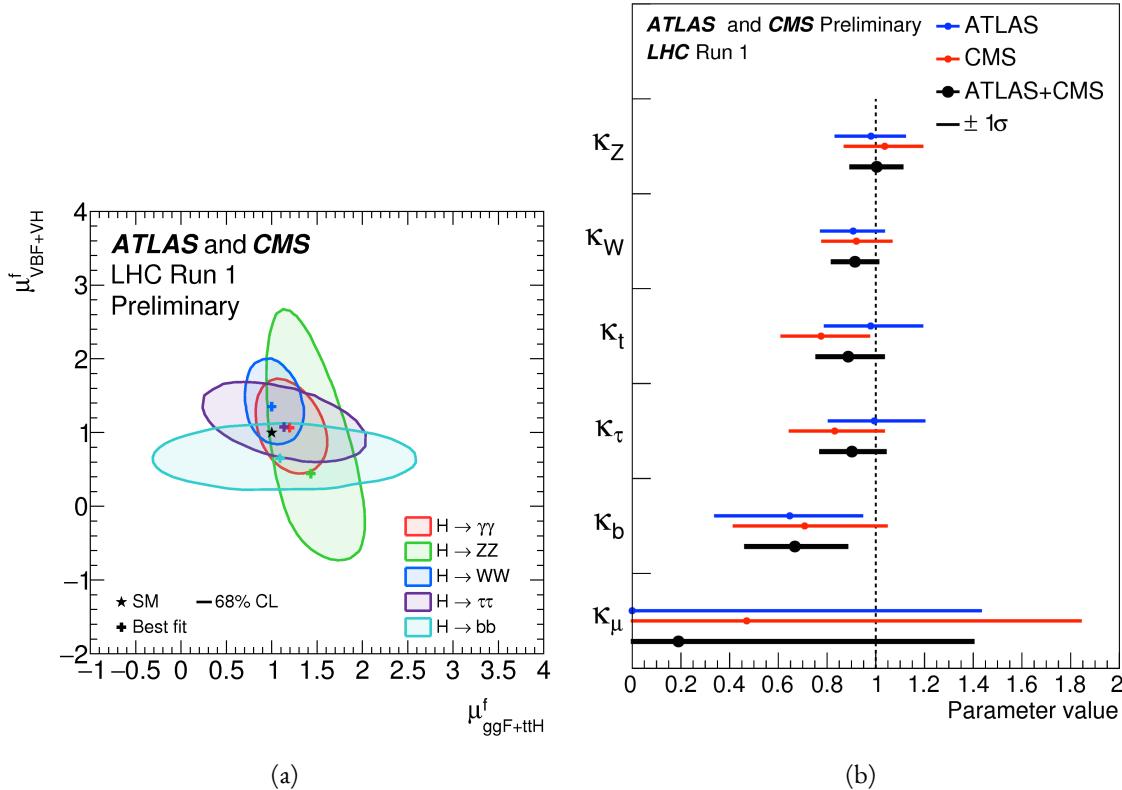

Figure 9.1: Combined ATLAS and CMS measurements in Run 1 for (a) Higgs signal strength in gluon fusion and VBF and (b) Higgs couplings normalized to their SM predictions

heavy narrow scalar resonances. The increase in center of mass energy in Run 2 allowed this analysis to quote upper cross section up to masses 3 TeV, while previous results from ATLAS in Run 1 only quote limits up to 2 TeV. The cross section of $\sigma(pp \rightarrow G_{\text{KK}}^* \rightarrow hh \rightarrow b\bar{b}b\bar{b})$ with $k/\bar{M}_{\text{Pl}} = 1$ was constrained to be less than 70 fb for masses in the range $600 < m_{G_{\text{KK}}^*} < 3000$ GeV. For the RSG model with $k/\bar{M}_{\text{Pl}} = 2$, cross sections limits between 40 fb and 200 fb are set for the mass range of $500 < m_{G_{\text{KK}}^*} < 3000$ GeV. The cross section upper limits for $\sigma(pp \rightarrow H \rightarrow hh \rightarrow b\bar{b}b\bar{b})$ ranges from 30 to 300 fb in the mass range of $500 < m_H < 3000$ GeV.

While there has been a rigorous program of measurements and searches involving the Higgs, there is still much room for improvement at the High Luminosity LHC (HL-LHC) and beyond. The measured signal strength for VBF production in $H \rightarrow WW^*$ still has a relative error at the level of 40%, largely dominated by statistical uncertainty. Projections for the HL-LHC show that the uncertainty on the VBF signal strength can be reduced to approximately 15% with 3000 fb^{-1} [132, 133]. This projection also assumes

2714 that theoretical uncertainties on the signal, which would be the largest contribution in the future dataset,
 2715 remain as they are now. Improvements in the theoretical understanding of the Higgs signal would also
 2716 reduce the signal strength uncertainty dramatically. Such precision results allow for measurements of the
 2717 Higgs coupling to vector bosons precise to the few percent level, therefore giving much power to constrain
 2718 or discover new physics.

2719 The prospects for detection of beyond the Standard Model resonant di-Higgs production at the HL-
 2720 LHC are also quite promising. Figure 9.2 shows projections for the discovery significance of RSG signals at
 2721 the HL-LHC in the $X \rightarrow HH \rightarrow b\bar{b}b\bar{b}$ search [133]. In all detector budget scenarios, a 1.5 TeV resonance
 is above or near 5σ significance, while a 2 TeV resonance is between $4-5\sigma$ except for the lowest budget.

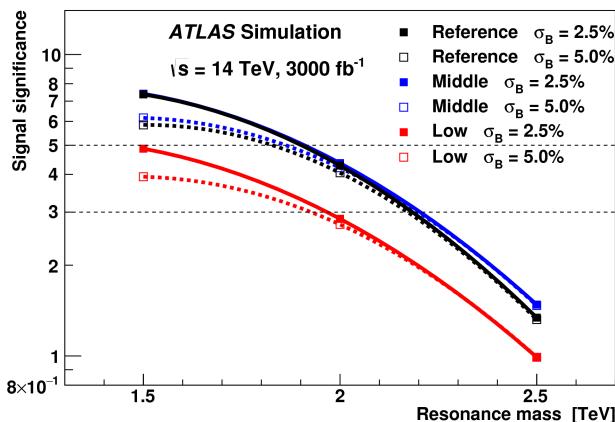

Figure 9.2: Discovery significance for RSG models at the HL-LHC in three different budget scenarios [133].
 Systematic uncertainties on the background prediction (σ_B) of 2.5% and 5.0% are both tested.

2722
 2723 The Higgs will continue to be an incredibly powerful tool in the understanding of nature at the HL-
 2724 LHC and beyond. Through both precision measurements and searches, the nature of electroweak symme-
 2725 try breaking will be better understood and the potential for the discovery of physics beyond the Standard
 2726 Model has never been greater.

2727

2728

b-tagging performance at high p_T

2729 One of the limiting factors of the signal acceptance in the $X \rightarrow HH \rightarrow b\bar{b}b\bar{b}$ search at high resonance
2730 masses is the degradation of the *b*-tagging efficiency for high p_T jets. This appendix presents a study of the
2731 underlying causes of this degradation.

2732 A.I CHANGES IN MV2 SCORE AT HIGH p_T

2733 The degradation of *b*-tagging at high p_T was studied in particular in the context of RSG models at high
2734 mass. Figure A.I shows the p_T of the leading track jet inside of the leading calorimeter jet in RSG events.
2735 At high $m_{G_{KK}^*}$, the p_T spectrum of track jets is much harder than at lower masses due to the increased
2736 Higgs p_T .

2737 Figure A.2 shows the MV2c2o algorithm score for the leading and subleading track jets inside of the
2738 leading calorimeter jet. In both cases, it can be seen that at higher RSG masses the MV2 score shifts towards
2739 more background like (negative) values. Additionally, this effect is more pronounced in the leading track

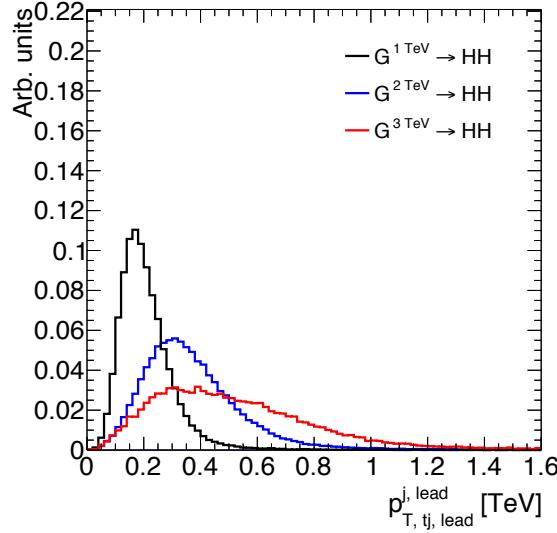

Figure A.1: p_T of the leading track jet in the leading calorimeter jet for different signal masses in RSG $c = 1$ models

²⁷⁴⁰ jet than the subleading.

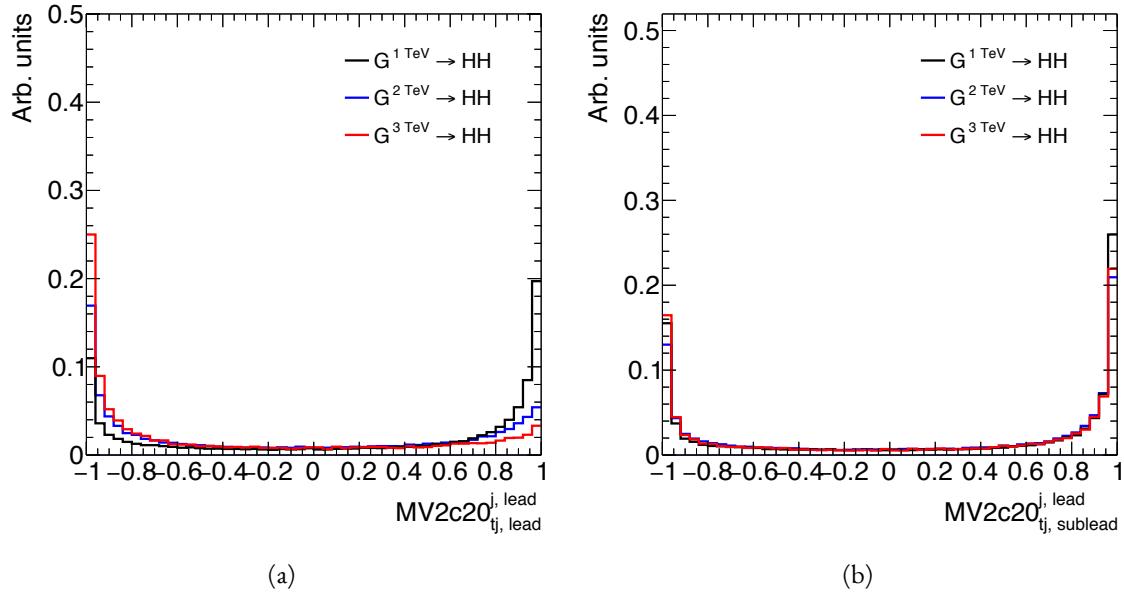

Figure A.2: MV2c20 score for the leading track jet (a) and subleading track jet (b) of the leading calorimeter jet for different signal masses in RSG $c = 1$ models

²⁷⁴¹ To understand what is causing this change in the MV2c20 score, the same comparisons can be made for
²⁷⁴² the input variables of MV2c20. The focus in these comparisons will be on the leading track jet as this is the
²⁷⁴³ one seen to have the largest difference in MV2 score. Figure A.3 shows the log likelihood ratio $\log(p_b/p_u)$

2744 from the IP₃D (three dimensional impact parameter) algorithm. At higher masses, the IP₃D likelihood
 2745 ratio distribution does become more background-like.

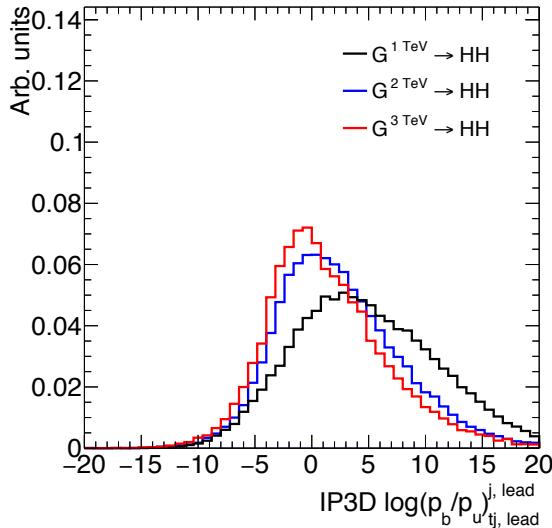

Figure A.3: IP₃D log-likelihood ratio ($\log(p_b/p_u)$) of the leading track jet in the leading calorimeter jet for different signal masses in RSG $c = 1$ models

2746 Figure A.4 shows the mass and number of tracks at the secondary vertex computed by the SV1 algorithm.
 2747 When there is no secondary vertex found, the algorithm assigns a default negative value for these quantities.
 2748 Both of these distributions show that there is a significantly larger fraction of jets where no secondary vertex
 2749 is found in the high mass samples compared to the $m_{G_{KK}^*} = 1$ TeV sample. The SV1 algorithm's inability
 2750 to find a secondary vertex could be an important factor in the overall MV₂ score shift, as this eliminates
 2751 eight of the input variables that would normally contribute information to the algorithm.

2752 Figure A.5 shows the same quantities for the JetFitter algorithm. In this case, there is also a change in
 2753 the fraction of jets which have their secondary vertices successfully reconstructed, but this change is not as
 2754 drastic as that seen in SV1. There is also an increase in the number of jets which have high values of mass.

2755 A.2 EFFECT OF MULTIPLE b -QUARKS INSIDE ONE JET

2756 One hypothesis for why the efficiency of b -tagging the leading track jet degrades is that at high masses, the
 2757 b quarks get close enough together that both of them are inside of the leading track jet. Because MV₂ is not

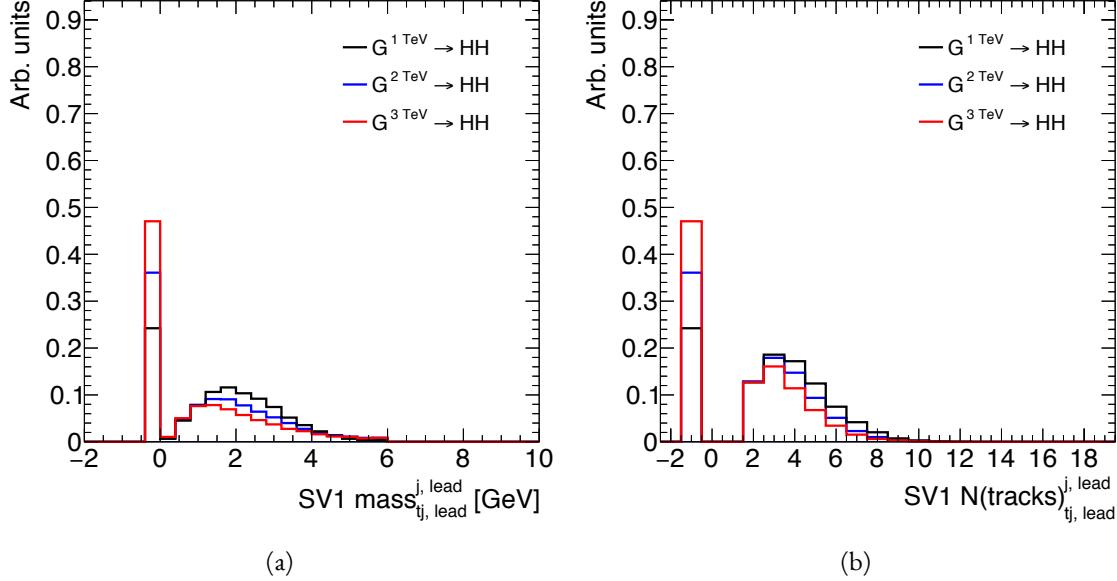

Figure A.4: Mass (a) and number of tracks (b) for the secondary vertices computed with the SV1 algorithm. When no secondary vertex is found, the quantities are assigned to default negative values.

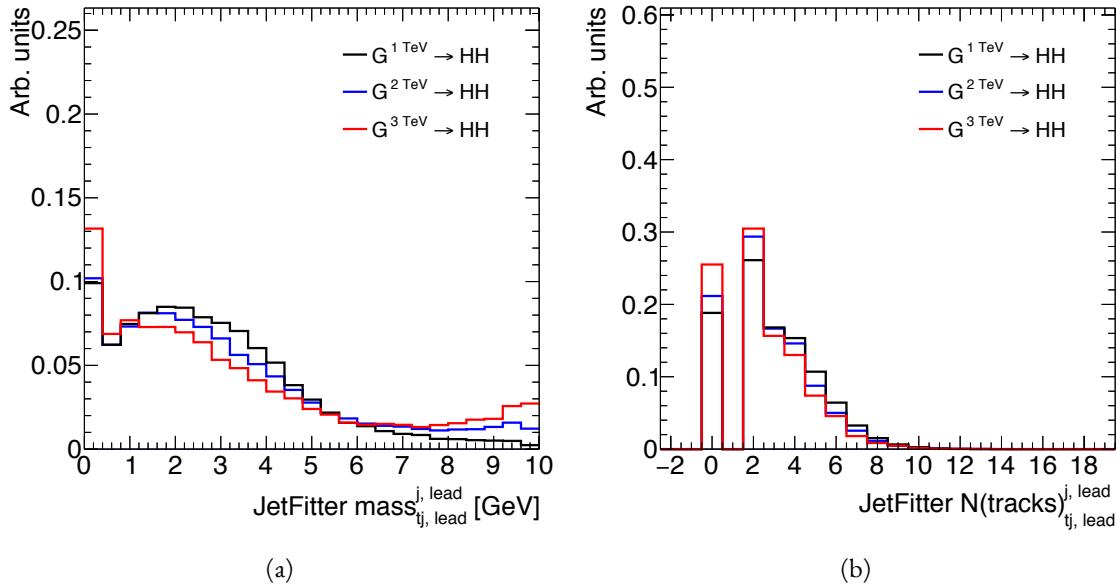

Figure A.5: Mass (a) and number of tracks (b) for vertices computed with the JetFitter algorithm. When no vertices are found, the quantities are assigned to default negative values.

2758 tuned for tagging multiple b quarks inside one jet, the tagging efficiency could degrade. Figure A.6 shows
 2759 MV2 scores and SV1 mass for cases where there are two b quarks at truth level within the radius of the

leading track jet compared to cases where there is only one true b ¹. This figure suggests that the presence

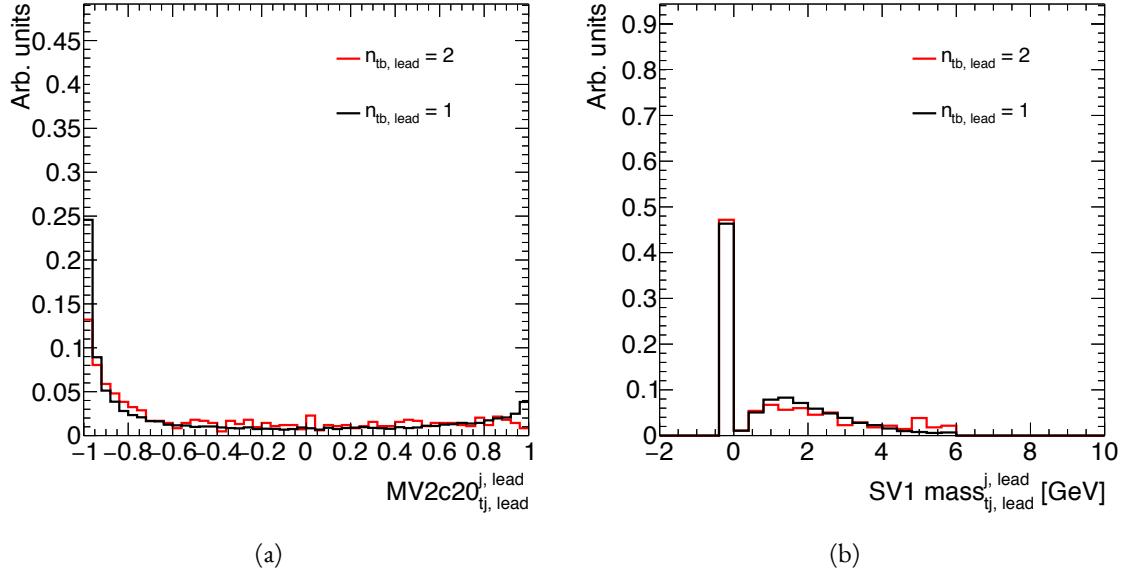

Figure A.6: MV₂c20 score (a) and SV1 mass (b) for leading track jets with two truth b quarks ($n_{tb, \text{lead}} = 2$) compared to those with only one truth b ($n_{tb, \text{lead}} = 1$).

of two b -quarks inside the leading jet is not the cause of the degradation in efficiency. There is a change in the shape of the MV₂ score distribution, but it is not nearly as pronounced as that seen in A.2 at higher masses. Additionally, the fraction of jets with no secondary vertex found is nearly identical in the track jets with two truth b -quarks.

A.3 CHANGES IN TRACK QUALITY AT HIGH p_T

Another hypothesis for the degradation of the b -tagging efficiency is a decrease in track quality for high p_T b jets. One way to check the overall quality of the tracking inside the jet is to investigate quantities related to the leading track inside of the track jet. Figure A.7 shows the fit χ^2/n_{DOF} and number of hits in the pixel detector for the leading track of the leading track jet. In both cases, the figure shows that in higher mass samples, the quality of the leading track inside of the track jet degrades substantially. The fit quality is lessened and the tracks have less hits in the pixel detector. This is likely due to the fact that at higher p_T ,

¹When two truth b quarks are required in the leading jet, the subleading jet is required to have zero. When one is required for the leading, one is also required for the subleading.

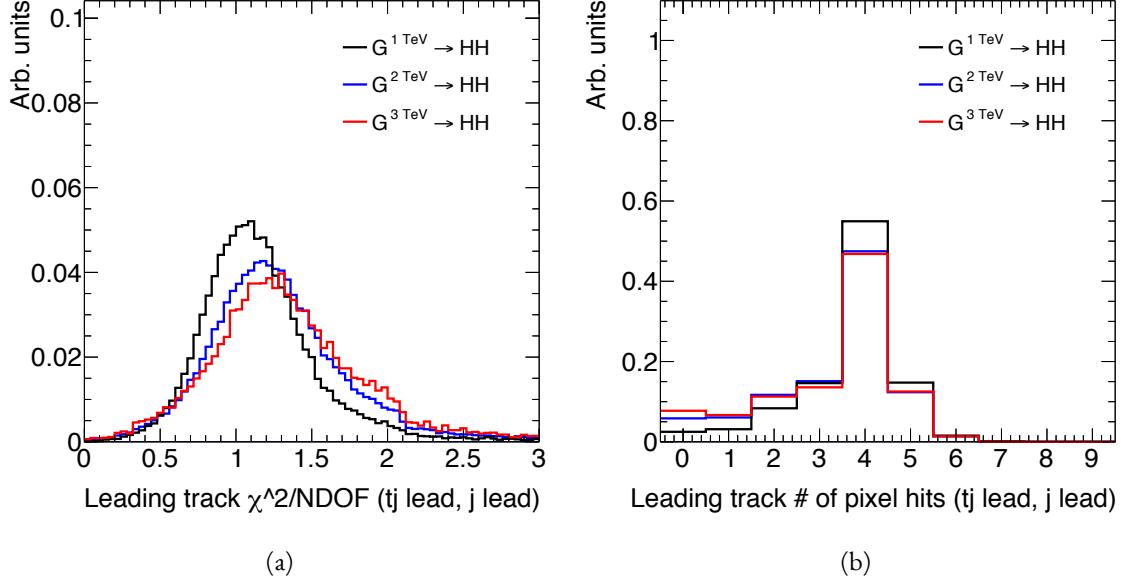

Figure A.7: Track fit χ^2/nDOF (a) and number of pixel detector hits (b) for the leading track of the leading track jet in different mass RSG $c = 1$ samples

the B -hadron will sometimes live long enough to miss the IBL and first pixel layer, thus decreasing the number of hits on the track.

To check whether this is the cause for the shift in the MV_2 score and the higher difficulty in reconstructing secondary vertices, jets whose leading track have at least four pixel hits are compared with those whose tracks have less than four pixel hits. The results for the MV_2 score and SV_1 mass are shown in figure A.8. Track jets where the leading track does not have at least four pixel hits are more likely to not have a secondary vertex reconstructed. Additionally, their MV_{2c2o} score is shifted more significantly to background-like values. This seems to confirm the hypothesis that degrading track quality is responsible for the lowered b -tagging efficiency at high p_T .

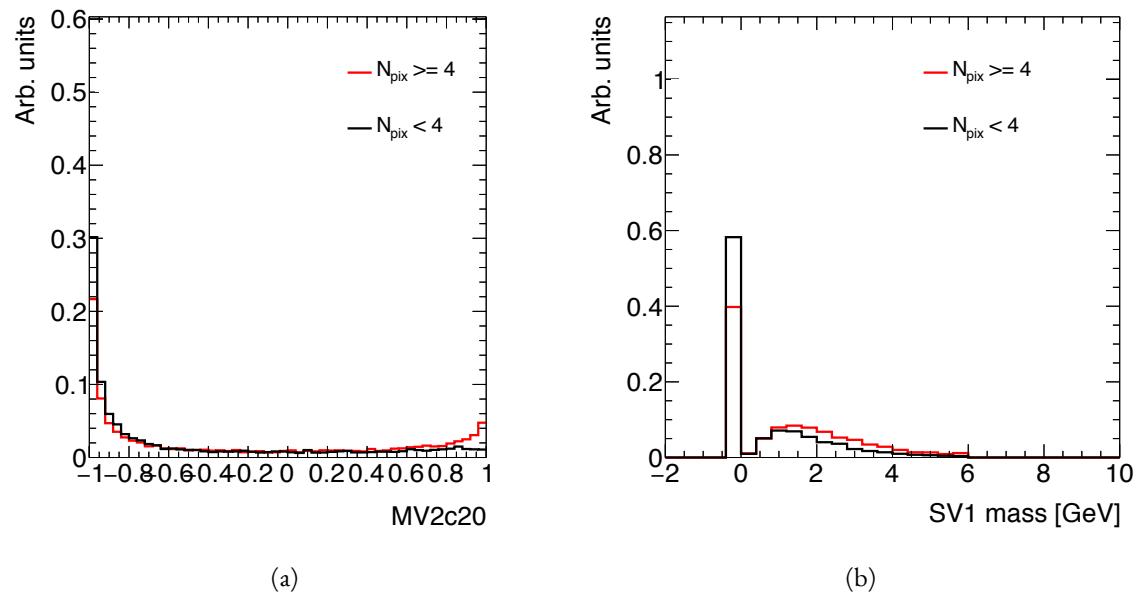

Figure A.8: MV₂c₂₀ score (a) and SV₁ mass (b) for leading track jets whose leading track jet has at least four pixel hits ($N_{\text{pix}} \geq 4$) compared to those which do not ($N_{\text{pix}} < 4$).
